## CONTENTS

FO REWORD ..... 10
Symbols and abbreviations ..... 12
Chapter Introduction and Basic Concepts ..... 17
Aims of the chapter ..... 17
1.1 Definition of inventory control systems ..... 17
1.2 The purpose of holding inventory ..... 17
1.3 Inventory costs ..... 18
1.4 Calculation of inventory average ..... 19

1. 5 Calculation of shortage average ..... 23
1.6 Some points on statistical distributions used in inventory control. ..... 25
1.7 Pareto Principle and ABC Analysis ..... 27
1.7.1 Steps in conduction ABC Analysis ..... 28
1.7.1 Control activities on different categories ..... 31
1-8 Inventory models classification ..... 32
Exercises ..... 33
Chapter $\sum_{\text {Deterministic Inventory Models }}$ ..... 37
Aims of the chapter ..... 37
2-1Economic Order Quantity(EOQ) model ..... 37
2-1-1 Assumptions of Classic EOQ model ..... 37
2-1-2 The maximum and the average of Inventory in EOQ model ..... 42
2-1-3 The reorder point(ROP) in EOQ model ..... 42
2-1-4 Sensitivity Analysis for EOQ Model ..... 45
2-1-4-1 Impact of Errors in $\mathrm{C}_{\mathrm{O}}$ ' Ch and D on Q and total cost ..... 46
2-1-4-2 Impact of Errors in $\mathrm{Q}_{\mathrm{w}}$ on total variable cost ..... 48
EOQ model for items with discrete order quantity( Q ) ..... 53
2-2-1Calculation of order quantity ..... 54
2-3 Safety stock model ..... 56
2-4 Economic Order Interval(EOI) Model-Single item ..... 58
2-5 EOQ Model -Back Order ..... 60
2-5-1 Average inventory and stockout level ..... 61
2-5-2 Optimal order quantity $(\mathrm{Q})$ and ..... 63
maximum stockout (b) in EOQ model with backorder ..... 63
2-5-3 Reorder level in EOQ with backorder model ..... 63
2-5-4 Optimal (Q) and (b) when $\pi \neq 0 \& \pi=0$ : ..... 64
2-2-5 Some comments on backordering ..... 67
2-6 On-hand inventory and on-order inventory ..... 71
2-7 EOQ Model -lost sale case ..... 72
2-8 Total Discount Model ..... 77
2-8-1 Quantity discount model -Ch variable ..... 79
2-8-1-1 The algorithm for finding optimal Q - ..... 79
Case 1: $\mathrm{C}_{\mathrm{h}}$ variable ..... 79
2-8-2 Quantity discount model -case II: $\mathrm{C}_{\mathrm{h}}$ Fixed ..... 81
2-9Converse of Discount Model (rate increase with quantity increase). 8 ..... 83
2-10 Incremental Discount Model ..... 86
2-10-1 The algorithm for finding optimal Q - incremental model ..... 87
2-11 EOQ Model with sale price(temporary discount) ..... 91
2-11-1 Summary : EOQ Model with sale ..... 94
2-12EOQ Model -permanent reduction price ..... 96
2-13 EOQ Model -known increase price ..... 96
2-14 Economic Production Quantity-single item ..... 100
2-14-1 EPQ -single item,stockout unpermitted ..... 100
2-14-1-1 The reorder point in EPQ model -single item ..... 102
2-14-2 Single-item EPQ model with backorders ..... 104
2-14-2-1 EPQ model with backorder - $\pi=0 \& \pi \neq 0$ ..... 105
2-15 Make or Buy Decision ..... 106
2-16 Economic Production Quantity:Multiple-item ..... 106
2-16-1 Multiple-item EPQ model: n machines for n products with noconstraints107
2-16-1 Multiple-item EPQ model: 1 machine for n products ..... 108
2-16-2-1 Multiple-item EPQ model: 1 machine $\& S_{i} \cong 0$ ..... 109
2-16-2-2 Multiple-item EPQ model: 1 machine $\& S_{i} \neq 0$.. ..... 113
2-17 Multiple-item EOQ model ..... 116
2-17-1 Unconstrianed multiple-item EOQ model ..... 116
2-17-2 Multiple-item EOQ model- annual number of orders the same for all ..... 116
2-17-2-1 Multiple-item EOQ Model : order cost independent ofnumber and quantity of items117
2-17-2-1 Multiple-item EOQ Model : separate order cost for items ..... 119
2-18 Deterministic continuous \& periodic review Models ..... 119
2-18-1 Deterministic continuous review=deterministic (r,Q) Model=Deterministic ( FOS)Model119
2-18-2 Deterministic periodic review=deterministic (R,T) Model=Deterministic ( FOI)Model120
2-19 Inventory Models for Deteriorating Items ..... 121
Exercises ..... 121
Chapter 3 Constrained Inventory Control Problems ..... 130
Aims of the chapter ..... 130
3-1 Lagrange multiplies technique and Karush-Kuhn-Tacker conditions 130
3-1-1 Nonlinear optimization problems with equality constraints ..... 131
3-1-2 optimization of nonlinear problems with in-equality constraints ..... 133
3-1-3 Nonlinear optimization problems with equality and in-equality
constraints ..... 135
3-1-4 Nonlinear optimization problems inequality constraints andnonnegative $x j^{\prime}$ s138
3-1-5 Interpretation of Lagrange multiplies ..... 138
3-2 Constraint in inventory systems ..... 139
3-2-1 Constraint on the space or surface of the warehouse ..... 140
3-2-2 Constraint on the budget ..... 144
3-2-2-1 The budget for ordering is exactly C dollars ..... 145
3-2-2-2 The budget for ordering is less than or equal to C. 146
3-2-3-1 Constraint on annual number of orders-Co negligible148
3-2-4 Constraint on the number of orders of multiple items having the samenumber of orders154
3-2-5 constraint on the cycle time of classic EOQ model-single item ..... 156
3-2-7 Multiple-constraint inventory models ..... 161
Exercises ..... 162

## FO REWORD

This book ${ }^{1}$ is the outcome of teaching a course titled "Inventory planning and control" for several years to B.S. students using many books especially the book written by Dr Tersine.

Thanks God for making me successful to present this work which I hope to be useful in both academic and industrial environments.

The book covers the classic topics in inventory control as well as some demand forecasting methods. The Persian version of the book has a chapter on MRP. But the author did not translate the chapter because there are many works available in the internet and in books.

Mr Masoud Hajghani gets the credit for the last part of Chapter 6 i.e verifying the forecasts. I would like to thank Mr Ali Bazargan who helped the author in some phases of editing.

The author would be pleased if the readers write him about any kind of deficiencies of the book.

## Chapter 1 Introduction \&

 Basic Concepts
## Chapter 1

## Introduction and Basic Concepts

## Aims of the chapter

This chapter deals with definitions and basic concepts needed in inventory control. The chapter also describes ABC analysis.

### 1.1 Definition of inventory control systems

A system of inventory control is compromised of people, devices, softwares and procedures for controlling inventories and orders in an institution. There are several items in an institution and each item has several units. The system is designed to decide which items (i), how much $\left(\mathrm{Q}_{\mathrm{i}}\right)$ and when to place the orders.

### 1.2 The purpose of holding inventory

The purpose of holding inventory in an organization could be the followings:
a)For finished products:

To cope with demand fluctuations,
To satisfy customers demand immediately,
To cope with production variations and halt
b)For In-Process Goods

To cope with production halt, c)For raw materials

To cope with production halt,
Using the vendor's discount.

Chapter 1 Introduction and Basic Concepts 18

### 1.3 Inventory costs

Inventory costs are associated with the operation of an inventory system and result from action or lack of action on the part of management in establishing the system (Tersine, 1994 p13). The costs are classified as fixed and variable. The former class is independent of the level of output and the latter changes in proportion to production output. The costs could be itemized as follows (Tersine, 1994 p 13 ):

1. Cost of ordering goods from outside or cost of machine setup for internal production.
2.The holding(carrying)cost which subsumes the costs associated with investing the inventory and maintaining the physical investment in storage. This costs includes such ones as insurance, tax, theft, fire, rent, heating, cooling and lighting. Carrying(holding ) costs are expressed as a proportion (I) of the total value of inventory. The cost of holding one unit per unit time (usually 1 year), denoted by Ch , is obtained by multiplying I times the unit price ( P ). Sometimes a fixed cost $(\mathrm{C})$ is added to $\mathrm{I} \times \mathrm{P}$, therefore:

$$
\begin{equation*}
\mathrm{C}_{\mathrm{h}}=\mathrm{IP}+\mathrm{C}, \quad 0<\mathrm{I}<1 \tag{1-1}
\end{equation*}
$$

where
$\mathrm{C}_{\mathrm{h}}$ Cost of holding one unit per unit time (usually 1 year)
$P$ unit price
C Fixed cost of holding for one unit per unit time
I Holding cost rate, cost of carrying $\$ 1$ of inventory for one unit of time.(e.g. 1 year)

For example, if the annual fixed cost for unit product is $\$ 30$ is incurred as well as the holding cost rate of $2 \%$ and the price is $\$ 400$ per ton then $\mathrm{C}_{\mathrm{h}}=30+0.02 \times 400=38$.

It is worth knowing that: Depreciation and salvage values are frequently incorporated in the insurance cost. However, if important they may be modeled mathematically . Moreover holding cost sometime is incorporated in $\mathrm{C}_{\mathrm{h}}$ as a function of the stored inventory and not as $I \times P$.
3.The purchase $\operatorname{cost}(\mathrm{P})$ is either the cost of purchase from external sources or the cost of production internally plus any freight cost (Terine, 1994, page 13).
4.The stockout or depletion cost occurs when a customer's order is not filled. In some models presented for inventory systems the stockout is not allowed and in some it is allowed as backorder or lost sale.
5. The cost of data processing and updating the information

It should be added that some textbooks itemize the cost as follows (Hajji, 2012):
a. costs related to the warehouse(Electricity, heating, cooling, rent, depreciation),
b. handling and transportation cost,
c. deterioration cost in inventory
d. cost of the obsolete inventory
e. The cost of money or capital held by the inventory
f. cost of insurance and tax
g. shortage cost
h. cost of purchase of materials
i. order/setup cost

### 1.4 Calculation of inventory average

Average inventory level in a warehouse and the average amount of shortages play important roles in mathematical models developed for inventory systems. Here a way to calculate the average amount of inventory is described. Suppose the function $I(t)$ describe the inventory of an item in a warehouse in terms of time (Fig 1.1). The inventory average during time interval $(0, T), \bar{I}$, is given by:

$$
\begin{equation*}
\bar{I} \text { or } \overline{I n v}=\frac{1}{T} \int_{0}^{T} I(t) d t \tag{1-2}
\end{equation*}
$$

Fig. 1.1 A time-related function of inventory

Figure 1.2 shows the average as the width of a rectangle having the same area as the function $\operatorname{inv}(\mathrm{t})$ has from 0 to T .

The calculation of the average amount of shortages during a period is calculated in a similar way.

## Example 1.1

If the amount of the inventory of an item in a store in terms of time (in month)is described by the function $e^{t}$, calculate the average inventory for the interval (0-4) months

Solution $\quad \bar{I}=\frac{1}{4} \int_{0}^{4} e^{\mathrm{t}} d t=13.4$. End of example $\boldsymbol{\Lambda}$

## Example 1.2

The inventory of an item changes as shown in the following figure.
Calculate the average of inventory during of the cycles i.e from 0 to T .

## Solution

Let variable $y$ denote the inventory and $x$ denote the time, then the equation of line AB could be written as:

$$
\begin{aligned}
& \frac{y-y_{B}}{x-x_{B}}=\frac{y_{A}-y_{B}}{x_{A}-x_{B}} \quad \Rightarrow \quad \frac{y-0}{x-T}=\frac{Q-0}{0-T} \\
& \Rightarrow y=\frac{-1}{T} Q(x-T)
\end{aligned}
$$

Therefore the equation of line $A B$ is $y=Q-\frac{Q}{T} x$, and the inventory average is calculated as follows:

$$
\bar{I}=\frac{1}{T} \int_{0}^{T}\left(Q-\frac{Q}{T} x\right) d x=\left.\frac{1}{T}(Q x)\right|_{0} ^{T}-\left.\frac{Q}{2 T^{2}} x^{2}\right|_{0} ^{T}=\frac{Q}{2} \bar{I}=\frac{Q}{2} .
$$

A simple way to calculate the average in this example is to note that the average is to divide the surface of the triangle by $T$ i.e. $Q \frac{T}{2}: \times \frac{1}{T}=\frac{Q}{2}$. The answer is equivalent to the calculation of the average of the maximum and minimum of inventory i.e. $\frac{0+Q}{2}=\frac{Q}{2}$.

## Example 1.3

If the holding cost of one dollar of an item as inventory is I dollars per year, the unit price of the item is P and $G(t)$ in the following figure is a function that gives the inventory stock level awaiting for use or marketing,

Find the average inventory in one year, annual holding cost and the holding cost for some finite time period like T (in year).

## Solution

annual average inventory $=\int_{0}^{1} \mathrm{G}(\mathrm{t}) \mathrm{dt}$,
annual holding cost $=I P \int_{0}^{1} G(t) d t$,
The average holding cost for a time T is: $T \times\left(I P \int_{0}^{1} G(t) d t\right)$

## Example 1.4

The following figure shows the inventory and shortage of an item (in tons). Find the annual average inventory and the related cost if the holding cost of one tone is $\$ 100$.

## Solution

annual average inventory $=\frac{3\left(\frac{2}{12}\right)+0.5\left(\frac{1}{12}\right)+2\left(\frac{2}{12}\right)+\frac{3}{2}\left(\frac{3}{12}\right)}{1}=\frac{\frac{15}{12}}{1}=\frac{15}{12}$
Holding cost $==\frac{15}{12} \times 100 \times 12=1500$

## 1. 5 Calculation of shortage average

Shortage average is needed to calculate shortage cost. Suppose $b(t)$ is a function of time denoting the shortage of an item at time $t$. The average amount of shortage during the time interval ( 0 T ) is given by

$$
\begin{equation*}
\bar{b}=\frac{1}{T} \int_{0}^{T} b(t) d t \tag{1-3}
\end{equation*}
$$

In Fig. 1-3 the negative inventory is indicative of shortage.

Fig. 1.3 shortage during a time period T

Note that $I(t)-b(t)$ is sometimes called the net inventory, where $I(t)$ is the level of inventory at time $t$.

## Example 1.5

In Example 1.4 find the average shortage per year

## Solution

$$
\text { annual average inventory }=\frac{3\left(\frac{2}{12}\right)+1\left(\frac{4}{12}\right)}{1}=\frac{\frac{10}{12}}{1}=\frac{10}{12}
$$

End of example

### 1.5.1 Unit normal loss integral

Since the calculation of the average shortages in some stochastic inventory models discussed in chapter 5 uses the so-called unit normal loss integral; this integral is introduced below

Let $S=\int_{x=a}^{\infty}(x-a) f(x) d x$ where a is a constant and $f$ is the probability density function of a normal distribution with mean $\mu$ and standard deviation $\sigma$, then:
$S=\int_{x=a}^{\infty}(x-a) \frac{1}{\sigma \sqrt{2 \pi}} e^{-\frac{(x-\mu)^{2}}{2 \sigma^{2}}} d x ;$
S is easily computed by the loss integral developed by Robert Schlaifer, described below.

Let $u=\frac{x-\mu}{\sigma} \Rightarrow x=\mu+u \sigma, d x=\sigma d u$. For $\mathrm{x}=\mathrm{a}$, the value of u would be $\frac{\mathrm{a}-\mu}{\sigma}$, which is denoted here it by k then:

$$
\frac{a-\mu}{\sigma}=\mathrm{k} \Rightarrow a=\mu+k \sigma \quad \Rightarrow x-a=(u-k) \sigma .
$$

Since $u=k$ is equivalent to $x=a$ then

$$
\begin{aligned}
& S=\int_{u=k}^{\infty}(u-k)(\sigma) \frac{1}{\sigma \sqrt{2 \pi}} e^{-\frac{u^{2}}{2}}(\sigma d u) \quad \Rightarrow \\
& S=\sigma \underbrace{\int_{u=k}^{\infty}(u-k) \frac{e^{-\frac{u^{2}}{2}}}{\sqrt{2 \pi}} d u}_{\mathrm{G}_{U}(k)}
\end{aligned}
$$

Let $G_{U}(k)=\int_{k}^{\infty}(u-k) \frac{1}{\sqrt{2 \pi}} e^{-\frac{u^{2}}{2}} d u$ then

$$
\begin{equation*}
S=\sigma G_{U}(k) \quad k=\frac{a-\mu}{\sigma} \tag{1-4}
\end{equation*}
$$

$\mathrm{G}_{\mathrm{U}}(\mathrm{k})$ as given above is called the unit normal loss integral and its values are given in Table A at the end of the book. It is worth knowing that it can also be calculated using the MATLAB command:
$\exp \left(-k^{\wedge} 2 / 2\right) / \operatorname{sqrt}\left(2^{*} \mathrm{pi}\right)-\mathrm{k}^{*}(1-\operatorname{normcdf}(\mathrm{k}))$

### 1.6 Some points on statistical distributions used in inventory control

Normal or Gaussian distribution is frequently used in inventory control for demand, lead time,...; however some other such as Poisson, uniform, lognormal and empirical distributions are also used. It is worth mentioning that

The distribution of the sum of several independent Poisson distributions is Poisson, however the product of a constant and a Poisson random variable does not have a Poisson distribution

The product of a constant and an exponential random variable has an exponential distribution, however the distribution of the sum of several exponential distribution is not exponential

### 1.6.1 The distribution of the sum and the product of two independent normal distribution

In probability theory, it is proved that the sum of two normally distributed independent random variables is normally distributed.

## Distribution of the product

The product of two normally distributed independent random variables $\mathrm{X} \& Y$ is not normally distributed, however, using Taylor series of $\mathrm{f}(\mathrm{x}, \mathrm{y})=\mathrm{xy}$ expanded about the mean of the variables i.e. $\mu_{X}, \mu_{Y}$ we have:
$\mathrm{W}=\mathrm{f}(\mathrm{x}, \mathrm{y}) \cong \mathrm{f}\left(\mu_{\mathrm{x}}, \mu_{\mathrm{Y}}\right)+\left[\left(\mathrm{x}--\mu_{\mathrm{X})} \mu_{\mathrm{Y}}+\left(\mathrm{Y}-\mu_{\mathrm{X}}\right) \mu_{\mathrm{X}}\right]\right.$
$\mathrm{f}\left(\mu_{\mathrm{X}}, \mu_{\mathrm{Y}}\right)=\mu_{\mathrm{X}} \times \mu_{\mathrm{Y}} \Rightarrow \mathrm{W} \cong\left(\mu_{\mathrm{Y}}\right) \mathrm{X}+\left(\mu_{\mathrm{X}}\right) \mathrm{Y}-\mu_{\mathrm{X}} \times \mu_{\mathrm{Y}}$
Now W has been approximated by a linear combination of $X$ and $Y$ .When X and Y are independent normal variables, this combination follows a normal distribution; that is why in some inventory books the product of 2 independent normal variables is assumed normal.

Seijas-Mac'ias \&Oliveira(2012) showed that for two uncorrelated normally distributed $X \& Y$, the more $\frac{\mu_{X}}{\sigma_{X}}$ and $\frac{\mu_{Y}}{\sigma_{Y}}$, the better fits the normal approximation to the distribution of $X \times Y$.

As an illustration, if annual demand ( $D$ ) for a product is normally distributed variable with mean 1000 and standard deviation 40, and variable the time needed for an order of the product to receive ( L ) is a variable which has normal distribution with mean 1 week and standard deviation $\frac{1}{4}$ week, the product $D \times \mathrm{L}$ is the demand during time L .

The following figure shows the histogram of the product of 100 random number from $N(1000,40)$ and 100 random number from $N\left(\frac{1}{52} \mathrm{yr}, \frac{0.25}{52} \mathrm{yr}\right)$ prepared using the following MATLAB commands:

D=normrnd(1000,40,100,1);L=normrnd(1/52,.25/52,100,1);W=D.*L;hist(W)

Fig. 1.4 The histogram of the product of 2 normal distributions

The histogram indicates that the consumption during time L is well approximated by a normal distribution.

### 1.7 Pareto Principle and ABC Analysis

Since the so-called ABC analysis is ABC is useful for analyzing the inventories in an institution, it is deal with below.

ABC analysis is a categorization method in which inventory is classified into A, B and C category with A being the lowest quantity, highest value. C being the highest quantity and lowest value. The purpose of this analysis is to help the managers identify those items that represent the large segment of the inventory costs in order to better manage these resources. It allows different inventory management techniques to be applied to different segments of the inventory in order to increase revenue and decrease costs.

Although the ABC analysis has had some modifications from the date it was developed, but the steps of the conventional method is described here after stating a related principle i.e. the Pareto principle.

## Pareto Principle

The Pareto principle, named after esteemed scientist Vilfredo Pareto (1848-1923) specifies that within any system or organization a small portion of input has the highest value and output. Actually ABC analysis could be considered an application of this principle. The criterion for categorization might be such things as delivery time as well as dollar value. The following is a sample categorization in a company:
' A ' items include the materials or components are necessary for production and have a long delivery time or a high value. The lot containing these items is delivered to the warehouse from which they are delivered to the production and repair departments with sealed or signed official sheets.
' B ' items include the production materials or components which have a medium delivery time or value. The control of these items is done by the direct supervisor of the department.
'C' items include regular standard components or materials whose delivery time is short or their value is low. When the order is received, they are submitted to the warehouse or the department depending on the type. When the inventory of the item reaches a small amount, an order is placed. A very low control is applied in these items

In the ABC analysis described below, the inventory items are listed and the annual consumption value of each item (Annual unit usage $\times$ unit cost/price). Very important items(A) items, medium important items and relatively unimportant items(C) could be identified after prepar ing the table and the graph for the ABC analysis.

The proportion of A, B and C items can be identified from a graph similar to Fig 1-4 and more control and energy applied on important items.

### 1.7.1 Steps in conduction ABC Analysis

1.Enlist items.
2. Estimate annual consumption - Unit wise.
3.Determine unit price of each item - .
4. Multiply the results of steps(2) \& (3) to obtain annual usage value
5. Arrange in descending order.
6. Calculate cumulative usage value percentages.
7. Graph cumulative usage value percentage against cumulative item percentage.

Note that $\mathrm{A}, \mathrm{B}$ and C categories are identified according the higherlevel management viewpoints. For example one manager may place the items with $80 \%$ of value in category A, the items with $15 \%$ of value in category $B$, the items with $5 \%$ of value in category $C$; the other one might choose the percents 70,20 and 10 for this purpose.

Fig 1-4 item classification in ABS analysis

## Example 1.6

Perform an ABC analysis on the products given following table

| Product <br> no. | 4837 | 9261 | 4395 | 3521 | 5223 | 5294 | 6081 | 4321 | 8046 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Annual <br> usage | 685 | 371 | 129.2 | 62 | 1266.7 | 962.5 | 1822.6 | 5100 | 25.8 |
| Unit <br> price | 12 | 8.6 | 131.8 | 91.8 | 32 | 101.8 | 4.8846 | 0.88 | 622.5 |

| Product no. | 9555 | 2926 | 1293 |
| :--- | :--- | :--- | :--- |
| Annual usage | 862 | 1940 | 967 |
| Unit price | 18.1 | 0.38 | 2.2 |

## Solution

The result of performing Step 4 of ABC analysis is seen in Row 4 of Table 1.1.

Table 1.1 The inventory items of a company

|  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Product <br> no. | 4837 | 9261 | 4395 | 3521 | 5223 | 5294 | 6081 | 4321 | 8046 |
| Annual <br> usage | 685 | 371 | 129.2 | 62 | 1266.7 | 962.5 | 1822.6 | 5100 | 25.8 |
| Unit <br> price | 12 | 8.6 | 131.8 | 91.8 | 32 | 101.8 | 4.8846 | 0.88 | 622.5 |
| Annual <br> value | 8220 | 3190.6 | 17028.56 | 5691.6 | 40534.4 | 97982.5 | 8902.7 | 4488 | 16060.5 |

| Chapter 1 Introduction and Basic Concepts | 30 |

|  | 10 | 11 | 12 |  |
| Product no. | 9555 | 2926 | 1293 |  |
| Annual usage | 862 | 1940 | 967 |  |
| Unit price | 18.1 | 0.38 | 2.2 |  |
| Annual value | 15602.2 | 737.2 | 2127.4 |  |

Table 1-2 shows the result of performing Steps 5\&6:

| Table 1-2 |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Rank <br> (J) | NO. in <br> Table 1-1 | Product NO. | Annual Value (\$) | Cum. Annual Value(\$) | Cum. Annual Value(\%) | $\begin{aligned} & \text { Cum Item } \\ & \text { NO.(\%) } \\ & \frac{\mathrm{j}}{12} \times 100 \\ & \hline \end{aligned}$ |
| 1 | 6 | 5294 | 97982.5 | 97982.5 | $\begin{aligned} & \frac{97982.5}{220565.66} \times 100 \\ & =44.423 \end{aligned}$ | $\frac{1}{12}=8.3$ |
| 2 | 5 | 5223 | 40534.4 | 138516.9 | $\begin{aligned} & \frac{138516.9}{220565.66} \times 100 \\ & =62.801 \\ & \hline \end{aligned}$ | $\frac{2}{12}=16.6$ |
| 3 | 3 | 4395 | 17028.56 | 155545.46 | 70.521 | $\frac{3}{12}=25$ |
| 4 | 9 | 8046 | 16060.5 | 171605.96 | 77.803 | 33.3 |
| 5 | 10 | 9555 | 15602.2 | 187208.16 | 84.876 | 41.7 |
| 6 | 7 | 6081 | 8902.7 | 196110.86 | 88.913 | 50 |
| 7 | 1 | 4837 | 8220 | 204330.86 | 92.639 | 58.3 |
| 8 | 4 | 3521 | 5691.6 | 210022.46 | 95.22 | 66.7 |
| 9 | 8 | 4321 | 4488 | 214510.46 | 97.255 | 75 |
| 10 | 2 | 9261 | 3190.6 | 217701.06 | 98.701 | 83.3 |
| 11 | 12 | 1293 | 2127.4 | 219828.46 | 99.666 | 91.7 |
| 12 | 11 | 2926 | 737.2 | 220565.66 | 100 | 100 |
| Sum |  |  | 220565.66 |  |  |  |

The management of the company decides to place the first 2 items of Table 1-2 with cumulative annual value $63 \%$ in Category A, the ne xt 3 others with cumulative annual value $22 \%$ in Category B and the rest in Category C with cumulative annual value $15 \%$. Table 1-3 and Fig. 1-6 shows the categories A , B, and C .

Table 1-3 the categories A , B, and C for Example 1-6.

| Table 1-3 the categories A , B, and C Ior Example 1-6. |  |  |  |
| :---: | :--- | :--- | :--- |
| Category | Product No from <br> Table1-1 | x-axis <br> number of products in the <br> category $/ 12(\%)$ | Y-axis <br> Annual value(\%) |
| A | 5223,5294 | $\frac{2}{12} \times 100=16.6$ | 62.801 |
| B | 4395,8046 <br> , 9555 | $\frac{3}{12} \times 100=25$ | $84.876-62.801=$ <br> 22.07 |
| C | 4321,3521, <br> $4837,6081,9261$, <br> 1293,2926 | $\frac{7}{12} \times 100=58.3$ | $100-84.876=$ <br> 15.12 |

## 31

Fig.1-5 Cumulative percentage of inventory products for Example 1-6

Therefore
$16.66 \%$ of the 12 items (Products No. 5223 and 5294) having $62.8 \%$ of the annual value constitutes category A.
$25 \%$ of the 12 items ( 3 products i.e. 4395,8046 and 9555 )having $22.07 \%$ of the annual value constitutes category B
$58.3 \%$ of the 12 items (seven products i.e. $4321,3521,4837$, 6081,9261 , 1293,2926 ) having $15.12 \%$ of the annual value constitutes category C. End of example

### 1.7.1 Control activities on different categories

Some of the control activities on the 3 categories are listed below:

## Control on Category A

Evaluation of forecasting methods and improving forecasts accuracy,

Updating the inventories of the items,
Frequent reviewing of demand, order quantity, safety stock to reduce the order quantity,
.attempt to reduce lead times.

## Control on Category B

The activities needed to perform on the items of Category B are similar to those applied on the previous group, but with with less frequent review and less accuracy.

## Control on Category C

Keeping a relatively large number of units on hand,
Simple inventory recordof the items or periodic review of the items
Making the inventory of the items easily accessible to the operators.
At the end of this section, it is worth knowing that recent researchers on inventory control analysis, do not necessary categorize the inventory of a firm into 3 categories. For example Ameri (2016) performed the analysis in a copper steel mill and suggested a fourcategory inventory control.

## 1-8 Inventory models classification

Many models have been developed for controlling the inventories in firms and organizations. These models are classified based on the decision conditions governing the inventory systems i.e. a) complete certainty b) uncertainty including complete uncertainty and risk.

In certainty conditions, parameters such as the amount of product demand, the waiting time to receive the ordered goods(lead time) are approximately constant; in other words regardless of small fluctuations, the parameters are almost constant and independent of time.

In day-today conversation, usually the two terms 'risk' and 'uncertainty' are used synonymously meaning 'a lack of certainty'. Let us divide the uncertainty conditions into complete uncertainty conditions and risk condition:

In complete uncertainty conditions there in no record of past data; therefore calculation of the occurrence probabilities for model
parameters is not possible. The decision under this condition is done using criteria such as Minmin and Mini-max.

In risk conditions, we have a record of past data which make it possible to calculate the probability of occurrence of alternative values of parameters such as demand and lead time.

Models such as Wilson-Harris model, safety stock, total discount model are used for certainty conditions.

Models such as single period model, periodic review model are used for uncertainty conditions.

It is worth mentioning that sometimes the inventory models are classified in two categories: deterministic and probabilistic inventory models.

It is advised, now at the end of this chapter, to make the data of a problem, when using a formula, have the same dimension; e.g. if the amount of daily demand and the annual holding cost are given, make both of them have the same time interval, say calculate annual demand to the same dimension as the holding cost has.

## Exercises

1-1 The following figure shows the amount of the inventory of a product in a warehouse. The per unit monthly shortage cost is $\$ 10$. Find the average shortage during the past 6 months, and the shortage cost during this period.

1-2. If the functions $I(t)$ and $D(t)$ denote the inventory and the demand for a product at time t . (answer choice a.)
a) $I(t)=0, D(t)>0$
b) $I(t)>0, D(t)>0$
c) $I(t)<0, D(t)<0$
d) $I(t)>0, D(t)<0$

1-3 If the inventory of an item follows the following function,
$\mathrm{I}(\mathrm{t})=[0.2 \times \ln (0.1 t)+0.2] e^{2(0.1 t) \ln (0.1 t)}$
Find the average inventory from $\mathrm{t}=3$ through $\mathrm{t}=6$.
1-4 Regarding the ABC analysis which of the following 4 choices is correct?
a) The items in Category A has the largest percent of items.
b) The items in Category C has the lowest percent of items.c) The items in Category $C$ has the largest percent of total annual consumption (in dollar).
d) The items in Category A has the largest percent of the total annual consumption (in dollar).

1-5 For which of the following cases, inventory control and planning is performed?
a)production equipment and tooling, raw materials, final products, in-process products
b)production equipment and tooling, raw materials, final products, tooling for services
c)tooling for services, raw materials, final products

> If the doors of heavens and earth are closed to someone, then he chooses piety, God shall relieve him

## Chapter2

 Deterministic Inventory Models
## Chapter 2

## Deterministic Inventory Models

## Aims of the chapter

This chapter introduces several models for inventory management under conditions of certainty: Economic order quantity model, Safety stock model Back -order model, lost sale model,...

## 2-1Economic Order Quantity(EOQ) model

Here the classic Economic Order Quantity (EOQ) model, which is the best known and the most ideal and fundamental inventory decision model, is described.

## 2-1-1Assumptions of Classic EOQ model

The following assumptions are present in the formulation of the classic EOQ model, in other words without these assumptions, the EOQ model cannot work to its optimal potential.

## Assumptions

-The conditions of certainty governs our inventory system. This mean that parameters such as demand rate (D), the lead time $\left(T_{L}\right)$, price $(\mathrm{P})$ are constants and not random variables.
-Orders placed arrive all at once.
-Price $(\mathrm{P})$ is fixed and does not change with the order quantity $(\mathrm{Q})$,
-No shortage occurs(replenishments arrive when the inventory level reaches zero.
-There is no constraint and restriction on capital, order quantity, warehouse space,...
-The goods have a largish lifetime and could be stored for a long time without deterioration, or the rate of deterioration is ignorable.

It is worth knowing that the purpose of inventory model is to plan the orders in such a way that the total cost of the inventory system is minimized. The output of the planning is to answer the following questions:

What is the quantity of each order ?
When to place an order? Every T-time period ?or when the inventory reaches a specified amount?

## List of Symbols

$\mathrm{C}_{\mathrm{h}} \quad$ Carrying (holding) costs, the cost of holding one unit per unit time (usually 1 year)
$\mathrm{C}_{0} \quad$ Cost of placing an order
D Demand rate, demand per unit time
EOQ Economic Order Quantity, amount of economic order
I a proportion of the total value of inventory, the cost of holding one dollar per unit time (usually 1 year)
$\bar{I} \quad$ Average inventory
m Number or orders placed per unit time
P Price
Q Order quantity
Q* Optimal quantity for orders
$\mathrm{Q}_{\mathrm{W}} \quad$ Optimal quantity for orders derived from Wilson formula
ROP Re-order Point
T Order interval, time between placing 2 successive orders or between arrival of 2 successive orders, the time required for
$\mathrm{L}=\mathrm{T}_{\mathrm{L}} \quad$ Lead time
TC Total cost of inventory system per unit of time
TVC Total variable cost of inventory system per unit of time

The total cost of inventory systems is the sum of the ordering, holding, and purchase costs. By multiplying the average annual inventory and the annual holding cost per unit product $\left(\mathrm{C}_{\mathrm{h}}\right)$, the annual holding cost is calculated on the average. Figure 1-2 shows the
level of inventory based on the above assumptions for the EOQ model.

It could easily be shown (see Example 1-2) that the average inventory per cycle is the quotient of the area of the triangle and its base leg ;here it will be equal to:

$$
\frac{Q}{2}=\frac{Q+0}{2}=\frac{\text { Max inventory }+ \text { Min inventory }}{2} .
$$

Given the annual demand (D)for a product with unit price P , order quantity $(\mathrm{Q})$ and cost of placing each order( $\left.\mathrm{C}_{0}\right)$, the annual order cost would be $\frac{D}{Q} C_{O}$ and the annual total cost of the inventory system is:

$$
\begin{equation*}
\mathrm{TC}=\mathrm{C}_{\mathrm{O}} \frac{\mathrm{D}}{\mathrm{Q}}+\mathrm{C}_{\mathrm{h}} \frac{(\mathrm{Q}+0)}{2}+\mathrm{PD} \tag{2-1}
\end{equation*}
$$

Note that stockout cost is not included here, because it was assumed that stockouts are not permitted in this model. If the order quantity ( Q ) is a continuous variable, since $\frac{d^{2} T C}{d Q^{2}}=\frac{C o D}{Q^{3}}>\cdot$, the function TC has a minimum. The optimal Q , is derived from $\frac{d T C}{d Q}=0$.

$$
T C=C_{O} \frac{D}{Q}+C_{h} \frac{Q}{2}+P D, \quad \frac{d T C}{d Q}=0 \Rightarrow Q^{*}=\sqrt{\frac{2 D C_{O}}{C_{h}}}
$$

Then in the classic Inventory model, the optimal order quantity $\left(Q^{*}\right)$ which is also called economic order quantity and denoted by $Q_{W}$ or $E O Q$ is equal to:

$$
\begin{equation*}
Q_{W}=E O Q=\sqrt{\frac{2 D C_{O}}{C_{h}}} \tag{2-2}
\end{equation*}
$$

Thi is also called Wilson inventory formula or Wilson-Harris formula.

Fig.2-2 The components of annual total cost of an inventory system
The total inventory cost per year (TC) and its 3 components are depicted by Fig. 2-2. As the figure shows the minimum of TC occurs at the intersection of the holding cost and the order cost i.e. at the intersection of $C_{O} \frac{D}{Q}$ and $C_{h} \frac{Q}{2}$ :

$$
C_{O} \frac{D}{Q}=C_{h} \frac{Q}{2} \Longrightarrow Q=\sqrt{\frac{2 D C_{O}}{C_{h}}}=Q_{W} .
$$

Note that,
1)As it is evident from Fig. 2-2,
when $Q<Q_{W}$, the annual order $\operatorname{cost}\left(\right.$ i.e. $\mathrm{C}_{\mathrm{O}} \frac{\mathrm{D}}{\mathrm{Q}}$ ) will exceed the annual holding cost (i.e. $\mathrm{C}_{\mathrm{h}} \frac{\mathrm{Q}}{2}$ )
when $\mathrm{Q}=Q_{W}$, the order cost will be equal to the annual holding cost.
when $Q>Q_{W}$, the order cost will be greater than the annual carrying $\operatorname{cost}\left(\right.$ i.e. $\mathrm{C}_{\mathrm{h}} \frac{\mathrm{Q}}{2}$ ).
2)The optimal order quantity in this model i.e. $Q_{W}$ is the point where the annual holding cost and the annual order cost are equal.

Now substituting $\mathrm{Q}=Q_{W}$ in relationship 2-2 results in:

$$
T C^{*}=\sqrt{2 D C_{O} C_{h}}+P D=C_{h} \times Q_{W}+P D
$$

Denoting the first part of this relationship by $T C_{W}$, we would have

$$
\begin{equation*}
T C_{W}=\sqrt{2 D C_{O} C_{h}}=C_{h} \times Q_{W} \tag{2-3}
\end{equation*}
$$

Optimal number of orders placed each year (m) would be:

$$
\begin{equation*}
m^{*}=\frac{D}{Q^{*}} \tag{2-4}
\end{equation*}
$$

and the interval time between successive orders ( T ) in its optimum state is $\quad T^{*}=\frac{1}{m^{*}}=\frac{Q^{*}}{D} \Rightarrow$

$$
\begin{equation*}
T^{*}=\sqrt{\frac{2 C_{O}}{D C_{h}}} \tag{2-5}
\end{equation*}
$$

In this model $T^{*}$ is also one cycle time in the optimum state and also the time required for consumption of $\mathrm{Q}^{*}$.

Chapter 2 Deterministic Models

## 2-1-2 The maximum and the average of Inventory in EOQ model

In the EOQ model when the quantity of each order is $Q_{W}$, the maximum inventory in the warehouse ( $\mathrm{I}_{\max }$ ) would be $Q_{W}$ and the average inventory ( $\bar{I}$ )would be $\frac{Q_{W}}{2}$.

$$
\begin{equation*}
\text { optimal } \bar{I}=\bar{I}^{*}=\frac{Q_{w}}{2}=\sqrt{\frac{C_{0} D}{2 C_{h}}} \tag{2-6}
\end{equation*}
$$

## 2-1-3 The reorder point(ROP) in EOQ model

If the time interval between placing an order until receipt of the products by the customer, known as the lead time and denoted here by $\mathrm{T}_{\mathrm{L}}$, is less than cycle time T (see Fig 2-3), the reorder point (ROP)

Fig. 2-3 Reorder point in the classic EOQ model $\left(T_{L}<T\right)$
is calculated as follows:

$$
\tan \alpha=D=\frac{A B}{B C} \Rightarrow D=\frac{R O P}{T_{L}} \Rightarrow R O P=D T_{L} .
$$

When $T_{L} \geq T$,as shown in Fig. 2-4, the orders arrive at points A, B, C, ...

Fig. 2-4 Reorder point in the classic EOQ model $\left(T_{L} \geq T\right)$

When the order arrives at B , then ROP equals demand times the time interval PA which is equal to $T_{L}-T$; therefore
$R O P=D\left(T_{L}-T\right)=D T_{L}-D T=D T_{L}-Q$
and in the optimal case $D T^{*}=Q^{*}$ and $R O P=D T_{L}-Q^{*}$.

Generally $R O P=D T_{L}-K Q^{*}$
where $K$ is $K=\left[\frac{T_{L}}{T}\right]$ i.e. the biggest integer number equal to or less than $\frac{\mathrm{T}_{\mathrm{L}}}{\mathrm{T}}$ (Patel, 1986).

Then in the classic EQQ model:
$R O P=\left\{\begin{array}{cc}D T_{L} & T_{L}<T^{*} \\ D T_{L}-K Q_{W}\end{array} \quad\left(K=\left[\frac{T_{L}}{T^{*}}\right] \leq T_{L}\right) \quad T_{L} \geq T^{*}\right.$
where
$K$ is the integer part of the ratio of lead time and cycle time.

Note that:
-When replacing the parameters in formulas, their dimensions must agree; e.g. if D is given per month and $\mathrm{C}_{\mathrm{h}}$ is given in year, both must have the same time interval.
-If the amount of D in is dollars, the amount of Q will be in dollars.
-In this model the cycle time T , which is equal to the time interval between placing two successive orders, is equal to the time required to consume the amount ordered Q .

## Example 2-1

An item may be purchased for $\$ 20$ per unit. The order cost is $\$ 100$. The annual holding cost fraction is $10 \%$ and the monthly demand for the item is 500 . There is 265 working days and 12 month in a year.
a)Calculate the economic order quantity, total annual cost, the time interval between 2 successive orders, the annual number of orders and also the reorder point if the lead time is 25 days.
b) Calculate the reorder point if the lead time is 40 days.

## Solution

a)
$E O Q$ or $Q_{W}=\sqrt{\frac{2 D C_{O}}{C_{h}}}=\sqrt{\frac{2 * 500 * 12 * 100}{0.1 * 20}} \approx 775$
$T C^{*}=P D+\sqrt{2 D C_{O} C_{h}}=P D+C_{h} \times Q_{W}=20 \times 6000+$ $2 \times 775=121550$

$$
\begin{aligned}
& \mathrm{T}^{*}=\frac{775}{12 \times 500}=0 / 13 \mathrm{yr}=0 / 13 \times 265 \text { days }=35 \text { days } \\
& m^{*}=\frac{1}{T^{*}}=\frac{12 \times 500}{775} \cong 8 \\
& T^{*}>\mathrm{T}_{\mathrm{L}} \Rightarrow R O P=D T_{L}=\frac{6000}{265} * 25=566
\end{aligned}
$$

That is when the inventory reaches 566 units, an order off 775 has to be placed.
b) $T^{*}<\mathrm{T}_{\mathrm{L}} \Rightarrow R O P=D T_{L}-K Q_{W}=\frac{6000}{265} * 40-\left[\frac{T_{L}}{T^{*}}\right] Q_{W} \Rightarrow$ $R O P=906-\left[\frac{40}{35}\right] * 775 \cong 130$. End of example $\boldsymbol{\Lambda}$

## 2-1-4 Sensitivity Analysis for EOQ Model

Sensitivity analysis in a model determines how target variables are affected by changes or errors in input variables. It is a way to predict the outcome of a decision given a certain range of input variables. If while keeping the rest of inputs constant, a vast range of an input variable does not change the amount of output variable significantly, it is said the model is not insensitive to the input variable. If any change in the input variable changes the amount of output variable significantly, it is said the model not sensitive to the variable.

The EOQ model assumes that annual demand $D$, holding cost $C h$ and order cost $C_{o}$ are deterministic and without variation; however this section will analyze the impact of errors in determining the parameters $D, C_{h}$ and $C_{o}$ in EOQ model.

Chapter 2 Deterministic Models
2-1-4-1 Impact of Errors in $C_{0}$ ، Ch and D on Q and total cost

## Definition

The quotient of estimated Co $\left(\boldsymbol{C}_{\boldsymbol{o}}^{\prime}\right)$ to actual Co is denoted by $\boldsymbol{r}_{\boldsymbol{o}}$ and called the error factor of order cost:
$\mathrm{r}_{\mathrm{O}}=\frac{\text { estimated } \mathrm{C}_{\mathrm{O}}}{\text { actual } \mathrm{C}_{\mathrm{O}}}=\frac{\mathrm{C}_{\mathrm{O}}^{\prime}}{\mathrm{C}_{\mathrm{O}}}$
Similarly

$$
r_{h}=\frac{\text { estimated } \mathrm{C}_{\mathbf{h}}}{\text { actual } \mathbf{C}_{\mathbf{h}}}=\frac{C_{h}^{\prime}}{C_{h}} \quad r_{D}=\frac{\text { estimated } \mathbf{D}}{\text { actual } \mathbf{D}}=\frac{D^{\prime}}{D} .
$$

If error occurs in estimating or determining $\mathrm{D}, \mathrm{C}_{\mathrm{O}}$ and $\mathrm{C}_{\mathrm{h}}$ then to determine the order quantity $\mathrm{D}^{\prime}, \mathrm{C}_{\mathrm{O}}{ }^{\prime}$ and $c_{h}^{\prime}$ replace $\mathrm{D}, \mathrm{C}_{\mathrm{O}}$ and $\mathrm{C}_{\mathrm{h}}$ :

$$
\begin{equation*}
Q=\sqrt{\frac{2 D^{\prime} c_{O}^{\prime}}{c_{h}^{\prime}}}=\sqrt{\frac{2\left(D r_{D}\right)\left(C_{O} r_{O}\right)}{C_{h} r_{h}}}=Q_{W} \sqrt{\frac{r_{D} r_{O}}{r_{h}}} \tag{2-8}
\end{equation*}
$$

If no error occurs in estimating, then $r_{O}=r_{h}=r_{D}=1$.
The error fraction in order quantity is as follows

$$
\begin{equation*}
\text { Error fraction in } Q_{W}=\frac{Q-Q_{W}}{Q_{W}}=\sqrt{\frac{r_{D} r_{O}}{r_{h}}}-1 \tag{2-9}
\end{equation*}
$$

When the order quantity in this model is as much as $Q_{W}$, the variable cost totally is denoted here by $\mathrm{TC}_{\mathrm{w}}$. When the order quantity is less or more than the economic order quantity $\left(\mathrm{Q} \neq Q_{W}\right)$, the total variable cost denoted by $T V C(Q)$ could be calculated from

$$
\begin{equation*}
T V C(Q)=T C_{w} \sqrt{r_{D} r_{O} r_{h}} \tag{2-10}
\end{equation*}
$$

The error in the total variable cost is equal to $\mathrm{TVC}_{(\mathrm{Q})}-\mathrm{TC}_{\mathrm{w}}$ and the error fraction in then the optimal cost is as follows:

$$
\begin{equation*}
\text { Error fraction in } T C_{W}=\frac{T V C_{(Q)}-T C_{w}}{T C_{w}}=\sqrt{r_{D} r_{O} r_{h}}-1 \tag{2-11}
\end{equation*}
$$

## Note that:

The error in only one parameter results in the same error fraction in $T C_{W}$.

Example 2-2 If 90\% of the actual holding cost is inserted in the Wilson formula for order quantity, calculate the fraction of error in $\mathrm{Q}_{\mathrm{W}}$ and $T C_{W}$.

## Solution

$$
\text { Error fraction in } Q_{W}=\sqrt{\frac{r_{D} r_{O}}{r_{h}}}-1=\sqrt{(1 * 1) / 0.9}-1=-0.0541
$$

That is inserting $90 \%$ of the holding cost in the Wilson formula will cause $5.41 \%$ reduction in optimal order quantity. This will cause the error fraction in TCw to be:

Error fraction in $T C_{W}=\sqrt{r_{D} r_{O} r_{h}}-1=\sqrt{1 * 1 * 0.9}-1=0.949-1=-0.051$
End of example
The following table, shows the error fractions calculated for several error factors . (Error has occurred in only one and only one parameter: in D or $\mathrm{C}_{\mathrm{h}}$ or $\mathrm{C}_{\mathrm{O}}$ ). According to this table, if for example $r_{D}=0.9, \quad r_{o}=r_{h}=1$, the error fraction in $T C_{w}$ would be $-5.1 \%$ which coincides with Eq.2-11:

Error fraction in $T C_{W}=\sqrt{r_{D} r_{O} r_{h}}-1=\sqrt{0.9}-1=-0.051=-5.1 \%$

Chapter 2 Deterministic Models
According to the table if the error fraction in only one of the parameters D or $\mathrm{C}_{\mathrm{h}}$ or $\mathrm{C}_{0}$ occurs between $0.9-1.1 \%$ and the 2 others are free of error, the error fraction in TVC* would be as small as -5.1 $\%$ to $+4.9 \%$.

## 2-1-4-2 Impact of Errors in $Q_{w}$ on total variable cost

To deal with the impact of error in $\mathrm{Q}_{\mathrm{w}}$ on total variable cost notice that

$$
T C=C_{O} \frac{D}{Q}+C_{h} \frac{Q}{2} \quad \text { and } \quad Q^{*}=Q_{w}=\sqrt{\frac{2 D C_{O}}{C_{h}}}
$$

$T V C^{*}=T C_{w}=\sqrt{2 D C_{O} C_{h}}$
Now let $\beta=\frac{\mathrm{Q}}{\mathrm{Q}_{\mathrm{w}}}$ then it could be shown that
relative increase in TVC $=\frac{T V C(Q)-T C_{w}}{T C_{w}}=\frac{T V C(Q)}{T C_{w}}-1 \Rightarrow$ relative increase in TVC $=\frac{1}{2}\left(\frac{1}{\beta}+\beta\right)-1>0 \quad(2-12)$

## Proof:

$$
\begin{aligned}
\alpha & =\frac{T V C(Q)}{T C_{w}}
\end{aligned}=\frac{\frac{C_{O} D}{Q}+\frac{C_{h} Q}{2}}{\sqrt{2 D C_{O} C_{h}}}=\sqrt{\frac{\frac{D^{2} C_{O}^{2}}{Q^{2}}}{2 D C_{O} C_{h}}}+\frac{Q}{2} \sqrt{\frac{C_{h}^{2}}{2 D C_{O} C_{h}}} .
$$

Since $T C_{w}$ is the minimum of TVC then $T V C(Q)-T C_{w}>0$ and hence the relative increase in TVC i.e. $\frac{T V C(Q)-T C_{w}}{T C_{w}}>0$ for $Q \neq Q_{w}$.

End of proof.
The following table shows some $Q_{w}$ error factors and their corresponding relative increase in TVC. According to this table the error factors in the range $0.5 \mathrm{Q}_{\mathrm{w}}$ to 2 times $\mathrm{Q}_{\mathrm{w}}$,cause at most $25 \%$ increase in TVC.

| $Q_{w}$ <br> Error factor | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | $\ldots$ | 1 | 1.2 | 1.4 | $\ldots$ | 2 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Relative increase <br> in TVC(\%) | 405 | 160 | 81 | 45 | 25 |  | 0 | 1.7 | 5.7 | $\ldots$ | 25 |

As a sample computation, suppose $\beta=\frac{Q}{Q_{w}}=2$, then relative increase in the total variable cost is equal to $\frac{1}{2}\left(\frac{1}{\beta}+\beta\right)-1=\frac{1}{4}=\% 25$.

## Example 2-3

Using the data of the following table, find
a)Simultaneous effects of error in D and $\mathrm{C}_{0}$ on $Q_{w}$ and simultaneous effects of error in the 3 parameters on it,
b) The effect of error in holding cost $C_{h}$ on $Q_{w}$ and $T C_{w}$.

| parameter | Actual value | Estimated value |
| :--- | :--- | :--- |
| D | 2000 | 1000 |
| $\mathrm{C}_{\mathrm{h}}$ | 20 | 10 |
| $\mathrm{C}_{0}$ | 25 | 50 |

## Solution

a)
$r_{h}=\frac{C_{h}^{\prime}}{C_{h}}=\frac{10}{20}=\frac{1}{2} \quad r_{o}=\frac{C_{o}^{\prime}}{C_{o}}=\frac{50}{25}=2 \quad r_{D}=\frac{C_{D}^{\prime}}{C_{D}}=\frac{1000}{2000}=\frac{1}{2}$
Simultaneous effect of the errors in $\mathrm{D} \& \mathrm{C}_{\mathrm{O}}$ on $\mathrm{Q}_{\mathrm{w}}$
$=\sqrt{\frac{r_{O} r_{D}}{r_{h}}}-1=\sqrt{\frac{2 * 0.5}{1}}-1=0$
Simultaneous effect of the errors in all 3 parameters on $Q_{w}=$

$$
=\sqrt{\frac{\mathrm{r}_{\mathrm{o}} \mathrm{r}_{\mathrm{D}}}{\mathrm{r}_{\mathrm{h}}}}-1=\sqrt{\frac{2 * 0.5}{0.5}}-1=0.414 \text { or } 41.4 \%
$$

b)

The effect of error in all parameters on TVC $=\sqrt{r_{D} r_{O} r_{h}}-1$
The effect of error in $\mathrm{C}_{\mathrm{h}}$ on TVC $=$
$\sqrt{1 \times 1 \times \mathrm{r}_{\mathrm{h}}}-1=\sqrt{1 * 1 * 0.5}-1=-0.293$
or $29.3 \%$ reduction on TVC. End of example

## Example 2-4

If an order quantity equal to one half or 2 times the optimal value $Q_{W}$ is placed, what will be the effect on the total variable cost?

$$
\begin{aligned}
& \alpha=\frac{T V C(Q)}{T C_{w}}=\frac{1}{2}\left(\frac{1}{\beta}+\beta\right) \\
& \\
& \left\{\begin{array}{lll}
\frac{Q}{Q_{w}}=\beta=2 & \longrightarrow & \alpha=\frac{5}{4} \\
\frac{Q}{Q_{w}}=\beta=\frac{1}{2} \quad \longrightarrow & \alpha=\frac{5}{4}
\end{array}\right\}
\end{aligned}
$$

Figure 2-5 shows the relation between $\alpha=\frac{T V C(Q)}{T C_{w}}$ and $\beta=\frac{Q}{Q_{w}}$. According to the figure, $\frac{T V C(Q)}{T C_{w}}$ Is slightly sensitive to $\frac{Q}{Q_{w}}$ when $0.5 \leq \frac{Q}{Q_{w}} \leq 2$.

Fig. 2-5 The relationship between $\alpha$ and $\beta$.

## Example 2-5

An item is purchased for $\$ 2000$ per unit. The order cost is $\$ 4000$. The annual holding cost fraction is $20 \%$ and the annual demand for the item is 20000. What order cost incur+5\% in total variable cost compared to the optimum TVC?

## Solution

$$
\begin{aligned}
& \frac{T V C}{T C_{w}}=\frac{1}{2}\left(\frac{Q}{Q_{w}}+\frac{Q_{w}}{Q}\right) \quad \frac{T V C}{T C_{w}}=\alpha \quad \frac{Q}{Q_{w}}=\beta \\
& \alpha=\frac{1}{2}\left(\beta+\frac{1}{\beta}\right) \quad \Rightarrow \beta=\alpha \pm \sqrt{\alpha^{2}-1} \\
& T V C=T C_{w}+0.05 T C_{w} \quad \alpha=\frac{\mathrm{TVC}}{\mathrm{TC}}=1+0.05=1.05 \\
& \beta=1.051 \pm \sqrt{1.05^{2}-1} \Rightarrow \beta=1.37 \text { or } 0.73 \\
& Q_{w}=\sqrt{\frac{2 D C_{0}}{C_{h}}}=\operatorname{sqrt}\left(\frac{2 * 20000 * 4000}{0.2 * 2000}\right)=632 \\
& Q=\beta Q_{w} \cong 462 \text { or } 867 .
\end{aligned}
$$

Therefore placing an order of $Q=462$ or 867 units will have a total variable inventory cost equal to $1.05 T C_{w}$. This fact is shown in the figure below where the minimum occurs at $Q_{w}=632$.

Note that TVC $=(1-0.05) \mathrm{TC}_{\mathrm{w}}$ cannot be considered in this problem. (Why?)

## EOQ model for items with discrete order quantity( $Q$ )

When the order quantity is discrete rather than continuous and hence Q is a discrete variable, you cannot use differentiation approach to determine Q . Instead, the following approach could be used :

We know that $T C(Q)=\frac{C_{O} D}{Q}+C_{h} \frac{Q}{2}+P D$. Suppose the vendor supply an item in lots of size n only; therefore the order quantity Q has to be an integer multiple of $n$ i.e. $\mathrm{Q}=\mathrm{K} \times \mathrm{n}$ where $\mathrm{K}=1,2,3, .$. Let the optimum order quantity is $Q^{*}$ and the minimum cost is $\operatorname{TC}\left(Q^{*}\right)$; if one n is added to or deducted from $\mathrm{Q}^{*}$, the corresponding total cost would be greater or equal to $T C\left(\mathrm{Q}^{*}\right)$

$$
\begin{align*}
& T C\left(Q^{*}\right) \leq T C\left(Q^{*}+1 n\right) \\
& T C\left(Q^{*}\right) \leq T C\left(Q^{*}-1 n\right) \\
& \Rightarrow\left\{\begin{array}{l}
\frac{C_{O} D}{Q^{*}}+C_{h} \frac{Q^{*}}{2} \leq \frac{C_{O} D}{Q^{*}+n}+\frac{C_{h}\left(Q^{*}+n\right)}{2} \\
\frac{C_{O} D}{Q^{*}}+C_{h} \frac{Q^{*}}{2} \leq \frac{C_{O} D}{Q^{*}-n}+\frac{C_{h}\left(Q^{*}-n\right)}{2}
\end{array}\right. \tag{I}
\end{align*}
$$

The following inequalities are derived from EQ. I \&II:
$\left\{\begin{array}{l}Q_{W}^{2}=\frac{2 C_{O} D}{C_{h}} \leq Q^{*}\left(Q^{*}+n\right) \\ Q_{W}^{2}=\frac{2 C_{O} D}{C_{h}} \geq Q^{*}\left(Q^{*}-n\right)\end{array}\right.$
Proof for $\frac{2 C_{o} D}{C_{h}} \leq Q^{*}\left(Q^{*}+n\right)$ :
By multiplying $2 Q^{*}\left(Q^{*}+n\right)$ to both sides of inequality $\mathbf{I}$ :

$$
\begin{aligned}
& \text { Chapter } 2 \text { Deterministic Models } \\
& 2 C_{O} D\left(Q^{*}+n\right)+C_{h} Q^{* 2}\left(Q^{*}+n\right) \leq 2 Q^{*} C_{O} D+C_{h} Q^{*}\left(Q^{*}+n\right)^{2} \Rightarrow \\
& 2 C_{O} D Q^{*}+2 C_{O} D n+C_{h} Q^{* 3}+C_{h} Q^{* 2} n \\
& \quad \leq 2 Q^{*} C_{O} D+C_{h} Q^{* 3}+C_{h} Q^{*} n^{2}+2 C_{h} Q^{* 2} n \Rightarrow \\
& 2 C_{O} D n-C_{h} Q^{*} n^{2}-C_{h} Q^{* 2} n \leq 0 \Rightarrow \frac{2 C_{O} D}{C_{h}} \leq Q^{*}\left(Q^{*}+n\right)
\end{aligned}
$$

In a similar manner $\frac{2 C_{O} D}{C_{h}} \geq Q^{*}\left(Q^{*}-n\right)$ is derived. Therefore:

$$
\begin{equation*}
Q^{*}\left(Q^{*}-n\right) \leq Q_{W}^{2}=\frac{2 D C_{o}}{C_{h}} \leq Q^{*}\left(Q^{*}+n\right) \tag{2-13}
\end{equation*}
$$

Notice that when $n$ approaches zero, $Q^{*}=\sqrt{\frac{2 D C_{O}}{C_{h}}}=Q_{W}$.

## 2-2-1Calculation of order quantity

## Solution No. 1

$Q^{*}$ is obtained by solving the inequality 2-13 and noting that it is a multiple of n i.e. $Q^{*}=K n . K=1,2,3, \ldots$

## Solution No. 2

It can be shown mathematically that the best integer value is one of the two integers surrounding $\mathrm{Q}_{\mathrm{w}}$ (Peterson \& Silver, 1991, P187).

In other words from the two integer multiples of $n$ surrounding $\mathrm{Q}_{\mathrm{w}}$ (immediate value less than $\mathrm{Q}_{\mathrm{w}}$ or greater than $\mathrm{Q}_{\mathrm{w}}$ ), the one with less TVC is the solution to 2-13 (adopted from page 123,Smith ,1989 as referenced by Ericson, 1996 page 31)

## Example 2-6

An item is purchased for $\$ 100$ per unit. The order cost is $\$ 11$. The annual holding cost fraction is $10 \%$ and the annual demand for the
item is 1200 units. If the vendor provides lots of 50 units only, How many lots do we buy in each order to minimize te inventory total cost?

## Solution no.1:

The optimal order quantity $\mathrm{Q}^{*}$ satisfies

$$
\mathrm{Q}^{*}\left(\mathrm{Q}^{*}-\mathrm{n}\right) \leq \frac{2 \mathrm{DC} \mathrm{C}_{0}}{\mathrm{C}_{\mathrm{h}}} \leq \mathrm{Q}^{*}\left(\mathrm{Q}^{*}+\mathrm{n}\right) \text { and } \quad \mathrm{Q}^{*}\left(\mathrm{Q}^{*}-50\right) \leq \frac{2 \times 1200 \times 11}{10} \leq \mathrm{Q}^{*}\left(\mathrm{Q}^{*}+50\right)
$$

The following 2 inequalities have to be solved

$$
\mathrm{Q}^{* 2}-50 \mathrm{Q}^{*}-2640 \leq 0 \quad \mathrm{Q}^{* 2}+50 \mathrm{Q}^{*}-2640 \geq 0
$$

Solving Inequality $Q^{* 2}-50 Q^{*}-2640 \leq 0$

$$
\mathrm{Q}^{* 2}-50 \mathrm{Q}^{*}-2640=0 \text { has two answers }-32.14 \text { and } 82.4
$$

The sign of the inequality in different sub-interval is as follows

| Subinterval on Q | $-\infty$ |  | -32.14 | 82.14 | $\infty$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| sign |  | + |  | - |  |

Q cannot be negative therefore $0 \leq \mathrm{Q}^{*} \leq 82.14$.satisfies the inequality

Solving inequalit $Q^{* 2}+50 Q^{*}-2640 \geq 0$

$$
\mathrm{Q}^{* 2}+50 \mathrm{Q}^{*}-2640=0 \text { has two answers } 32.14 \text { and }-82.4
$$

The sign of the inequality in different sub-intervals is as follows

| Subinterval on Q | $-\infty$ | -82.14 | $32.14 \quad \infty$ |  |
| :---: | :--- | :--- | :--- | :--- |
| sign | + |  | - | + |

Q cannot be negative; therefore $Q^{*} \geq 32.1$. satisfies the inequality.
The answer lies in $0 \leq \mathrm{Q}^{*} \leq 82.14 \& \mathrm{Q}^{*} \geq 32.14$ that is

Chapter 2 Deterministic Models
$\mathrm{Q}^{*}$ lies In the interval $32.14 \leq \mathrm{Q}^{*} \leq 82.14$ and is also a multiple on 50 , therefore $Q^{*}=50$.

If the inequality were such that either 50 or 100 could have been the answer, we had to choose the one with less TVC.

## Solution no.2:

$\mathrm{Qw}=\sqrt{\frac{2 \mathrm{DC}_{\mathrm{O}}}{\mathrm{C}_{\mathrm{h}}}}=\sqrt{\frac{2 \times 1200 \times 11}{10}}=51.4$
Q*
The immediate value less than $\mathrm{Q}_{\mathrm{w}}$ is 50 and the immediate value greater than $\mathrm{Q}_{\mathrm{w}}$ is 100 ,

$$
\begin{gathered}
\operatorname{TVC}(\mathrm{Q}=50)=11 * \frac{1200}{50}+10 *\left(\frac{50}{2}\right)=514 \\
\operatorname{TVC}(\mathrm{Q}=100)=11 * \frac{1200}{100}+10 *\left(\frac{100}{2}\right)=632
\end{gathered}
$$

The one with less TVC is the answer i.e. $Q^{*}=50$.

## 2-3 Safety stock model

The difference between the classic EOQ model and the safety stock model is keeping an extra inventory known as safety stock( $\mathrm{SS}=\mathrm{M}$ )in the warehouse of this system to cope with variations of D and $\mathrm{T}_{\mathrm{L}}$ (Fig. 6.2)

Fig. 2-6 Safety Stock Model

If the order quantity is Q , the total inventory cost would be:

$$
\begin{array}{r}
T C=\frac{C_{0} D}{Q}+C_{h} \frac{M+M+Q}{2}+P D+P M \Rightarrow \\
T C=\frac{C_{0} D}{Q}+\frac{C_{h} Q}{2}+M C_{h}+P(D+M) \tag{2-15}
\end{array}
$$

The second derivative of $T C$ with respect to variable $Q\left(=\frac{C_{0} D}{Q^{3}}\right)$ is positive then TC has a minimum which satisfies $\frac{\mathrm{dTC}}{\mathrm{dQ}}=0$.

$$
\begin{aligned}
& \frac{\mathrm{dTC}}{\mathrm{dQ}}=0 \Rightarrow \mathrm{Q}^{*}=\mathrm{Q}_{\mathrm{W}}=\sqrt{\frac{2 \mathrm{DC}_{0}}{\mathrm{C}_{\mathrm{h}}}} \\
& \operatorname{TVC}\left(\mathrm{Q}^{*}\right)=\sqrt{2 \mathrm{DC}_{0} C_{h}}+M \mathrm{MC}_{\mathrm{h}}=C_{h}\left(Q^{*}+M\right)
\end{aligned}
$$

The reorder point in safety stock model is

$$
\mathrm{ROP}=\left\{\begin{array}{ll}
\mathrm{SS}+\mathrm{DT}_{\mathrm{L}} & \mathrm{~T}_{\mathrm{L}}<\mathrm{T}^{*} \\
\mathrm{SS}+\mathrm{DT}_{\mathrm{L}}-\mathrm{KQ}^{*}
\end{array} \quad\left(\mathrm{~K}=\left[\frac{\mathrm{T}_{\mathrm{L}}}{\mathrm{~T}^{*}}\right] \leq \mathrm{T}_{\mathrm{L}}\right) \quad \mathrm{T}_{\mathrm{L}} \geq \mathrm{T}^{*} \quad(2-16)\right.
$$

Where $\left[\frac{T_{L}}{T^{*}}\right]$ denotes the integer part of $\frac{T_{\mathrm{L}}}{T^{*}}$.
Note that when replacing the parameters in formulas, their dimensions must agree; e.g. if D is given per day and $\mathrm{T}_{\mathrm{L}}$ is given in year, both must have the same time unit; e.g. multiply D by N (the number working days in a year).

In this model the following formulae might be useful:

$$
\begin{align*}
& \text { Max inventory }=\mathrm{Q}_{\mathrm{W}}+\mathrm{SS}  \tag{2-17-1}\\
& \text { Min inventory }=\mathrm{SS} \tag{2-17-2}
\end{align*}
$$

$$
\begin{equation*}
\text { Inventory Average }=S S+\frac{\mathrm{Q}_{\mathrm{W}}}{2} \tag{2-17-3}
\end{equation*}
$$

## 2-4 Economic Order Interval(EOI) Model-Single item ${ }^{1}$

In this model the time interval between successive orders are the same and the main problem is determining the optimal interval(T) and the desired maximum inventory(Imax). Economic order interval is calculated by maximizing the total cost function. Under no stockout assumption, the annual total cost TC is:

Annual holding cost $=$
$C_{h} \times$ average annual inventoty $=C_{h} \frac{Q}{2}=C_{h} \frac{D T}{2}$
If T is given in year, the annual number of orders is $\mathrm{m}=\frac{1}{\mathrm{~T}}$ and therefore;

$$
\begin{equation*}
\mathrm{TC}=\mathrm{C}_{\mathrm{O}} \frac{1}{\mathrm{~T}}+\mathrm{C}_{\mathrm{h}} \frac{\mathrm{DT}}{2}+\mathrm{PD} \tag{2-18}
\end{equation*}
$$

taking the derivative of the function with respect to $\mathrm{T}: \frac{\mathrm{dTC}}{\mathrm{dT}}=0 \Rightarrow$

$$
\begin{equation*}
\mathrm{T}^{*}=\sqrt{\frac{2 \mathrm{C}_{\mathrm{o}}}{\mathrm{DC}_{\mathrm{h}}}} \tag{2-19}
\end{equation*}
$$

Replacing T with $\mathrm{T}^{*}$ in Eq. 2-18 gives optimal annual cost:
$\mathrm{TC}^{*}=\mathrm{DC}_{\mathrm{h}} \mathrm{T}^{*}+\mathrm{PD}=\mathrm{C}_{\mathrm{h}} \mathrm{Q}^{*}+\mathrm{PD}$
where (Tersine, 1994 page 136)

$$
\begin{equation*}
\mathrm{Q}^{*}=\mathrm{DT}^{*} \tag{2-21}
\end{equation*}
$$

[^1]Noting that the optimum occurs where the annual order cost equals annual holding cost, $\mathrm{TC}^{*}$ could also be calculated as follows:
$\mathrm{TC}^{*}=\frac{\mathrm{DC}_{\mathrm{h}} \mathrm{T}^{*}}{2}+\frac{\mathrm{DC}_{\mathrm{h}} \mathrm{T}^{*}}{2}+\mathrm{PD}=\mathrm{DC}_{\mathrm{h}} \mathrm{T}^{*}+\mathrm{PD}$.
The maximum inventory in this model must be large enough to satisfy demand during subsequent interval T and also during the lead time (Tersine,1994,page 136, Tersine, 1985,596)

$$
\begin{equation*}
\mathrm{E}=\mathrm{I}_{\text {max }}^{*}=\mathrm{DT}^{*}+\mathrm{DT}_{\mathrm{L}}=\mathrm{D}\left(\mathrm{~T}^{*}+\mathrm{T}_{\mathrm{L}}\right) \tag{2-22}
\end{equation*}
$$

or

$$
,_{\max }^{*}=\mathrm{Q}^{*}+\mathrm{DT}_{\mathrm{L}} \quad(2-23)
$$

Note that
-When replacing the parameters in formulas, their dimensions must agree; e.g. if D is given per month and TL is given in year, both must have the same time unit.

- In this model, there is no need to give a separate formula for reorder points(why?)
-If certainty conditions hold, there is no difference between the optimal T\&Q of classic EOQ model and those of EOI model.
- In probabilistic models there are models titled fixed order size and fixed order interval in which D and TL might be random variables. As will be dealt in the related chapter, in this case to determine T and $\mathrm{I}_{\text {Max }}$, the mean of D could be inserted in the above formulae. Further more, when placing an order, if the available inventory is A, then

$$
\begin{equation*}
\mathrm{Q}=\mathrm{I}_{\mathrm{Max}}-\mathrm{A} \tag{2-24}
\end{equation*}
$$

## Example 2-6

An item is purchased for $\$ 10$ per unit. The order cost is $\$ 30$. The annual holding cost per unit is $\$ 3$ and the annual demand for the item is 8000 units. If the lead time is 10 working days and there is 260 working days in a year, Find the time interval between 2 successive orders, the maximum inventory level and the annual total cost in the optimal state.

## Solution

$\mathrm{T}^{*}=\sqrt{\frac{2 \mathrm{C}_{\mathrm{O}}}{\mathrm{DC}}}=\sqrt{\frac{2 * 30}{8000 * 3}}=0.05 \mathrm{yr}=0.05 * 260=13$ days
${ }_{\text {Max }}=\mathrm{D}\left(\mathrm{T}^{*}+\mathrm{T}_{\mathrm{L}}\right)=8000\left(\frac{13+10}{260}\right) \cong 708$
$\mathrm{Q}^{*}=\mathrm{DT}^{*}=8000 * 0.05=400 \quad$ or
$\mathrm{Q}^{*}=\mathrm{I}_{\text {Max }}-\mathrm{DT}_{\mathrm{L}}=708-8000\left(\frac{10}{260}\right) \cong 400$
In this inventory system, every 13 working days an order of 400 units is placed. $\mathrm{TC}^{*}=\mathrm{C}_{\mathrm{h}} \mathrm{Q}^{*}+\mathrm{PD}=400 \times 3+10 \times 8000=$ 81200\$ per yr.

## 2-5 OQ Model -Back Order

In this model, any demand, when out of stock, is backordered and filled as soon as an adequate sized replenishment arrives (Peterson\&Silver, 1991 p 209). It is assumed that when we are out of stock the demand arrives with the same rate(see Fig. 2-7)

## Symbols

| $\pi$ | fixed stockout cost per unit |
| :--- | :--- |
| $\hat{\pi}$ | stockout cost per unit per year $(\hat{\pi} \neq 0)$ |
| b | maximum backordering (stockout) quantity |
| $\bar{b}$ | average backordering (stockout) quantity |
| s | maximum inventory in units |
| Q | Order quantity |

Fig. 2-7 EOQ Model with Back Order

## 2-5-1 Average inventory and stockout level

Below it is shown that :

Average inventory level per year ( $\bar{I}$ ) is given by:

$$
{ }^{-}=\frac{(\mathrm{Q}-\mathrm{b})^{2}}{2 \mathrm{Q}} \quad(2-25-1)
$$

Average stockout per year ( $\overline{\mathrm{b}}$ ) is given by:

$$
\overline{\mathrm{b}}=\frac{\mathrm{b}^{2}}{2 \mathrm{Q}} \quad(2-25-2)
$$

## Proof

Assuming the rate of demand and the rate of stockout are the same, in Fig. 2-7 we have:
$\frac{\mathrm{AO}}{\mathrm{OC}}=\tan \alpha=\mathrm{D}, \quad \mathrm{Q}=\mathrm{b}+\mathrm{s} \Rightarrow \mathrm{s}=\mathrm{Q}-\mathrm{b}=\mathrm{AO} \Rightarrow \mathrm{OC}=\frac{\mathrm{Q}-\mathrm{b}}{\mathrm{D}}$
$\overline{\mathrm{I}}=\frac{\text { Area of Triangle } O A C}{\text { time } \mathrm{T}}=\frac{\frac{1}{2}(\mathrm{AO})(\mathrm{OC})}{O C+C E}=\frac{\frac{1}{2}(\mathrm{Q}-\mathrm{b}) \frac{(\mathrm{Q}-\mathrm{b})}{\mathrm{D}}}{\mathrm{T}}=\frac{(\mathrm{Q}-\mathrm{b})^{2}}{2 \mathrm{TD}}$
$\mathrm{Q}=\mathrm{DT}$ then $\overline{\mathrm{I}}=\frac{(\mathrm{Q}-\mathrm{b})^{2}}{2 \mathrm{Q}}$,

Average stockout per year ( $\overline{\mathrm{b}}$ ):
$\overline{\mathrm{b}}=\frac{\text { Area of Triangle CEP }}{\text { time } \mathrm{T}}=\frac{\frac{\mathrm{CE} \times \mathrm{b}}{2}}{\mathrm{~T}}$
$\mathrm{CE}=\frac{\mathrm{b}}{\tan \alpha}=\frac{\mathrm{b}}{\mathrm{D}}$ then $\overline{\mathrm{b}}=\frac{\mathrm{b} \times \mathrm{b}}{2 \mathrm{TD}} \Rightarrow \overline{\mathrm{b}}=\frac{\mathrm{b}^{2}}{2 \mathrm{Q}}$. End of proof.

Costs:

Total cost includes total variable cost +PD

Total variable cost(TVC) is comprised of order cost, carrying cost and stockout cost.

Variable cost for one period $=C_{O}+C_{h} \bar{I} T+\widehat{\pi} \bar{b} T+\pi b$
Total annual cost $=C_{O} \frac{D}{Q}+C_{h} \overline{\mathrm{I}} \mathrm{T} \frac{\mathrm{D}}{\mathrm{Q}}+\frac{\mathrm{D}}{\mathrm{Q}} \widehat{\pi} \overline{\mathrm{b}} \mathrm{T}+\pi \mathrm{b} \frac{\mathrm{D}}{\mathrm{Q}}+\mathrm{PD}$

$$
\text { Since } \frac{\mathrm{DT}}{\mathrm{Q}}=1, \quad \overline{\mathrm{~b}}=\frac{\mathrm{b}^{2}}{2 \mathrm{Q}} \text { and } \overline{\mathrm{I}}=\frac{(\mathrm{Q}-\mathrm{b})^{2}}{2 \mathrm{Q}} \text { then }
$$

$$
\begin{equation*}
\mathrm{TC}(\mathrm{Q}, \mathrm{~b})=\frac{\mathrm{C}_{\mathrm{O}} \mathrm{D}}{\mathrm{Q}}+\mathrm{C}_{\mathrm{h}} \frac{(\mathrm{Q}-\mathrm{b})^{2}}{2 \mathrm{Q}}+\widehat{\pi} \frac{\mathrm{b}^{2}}{2 \mathrm{Q}}+\frac{\pi \mathrm{bD}}{\mathrm{Q}}+\mathrm{PD} \tag{2-26}
\end{equation*}
$$

## 2-5-2 Optimal order quantity $(Q)$ and maximum stockout (b) in EOQ model with backorder

Differentiating from Eq. 2-26 with respect to Q and b and solving the following simultaneous equations, yields the optimal answers:

$$
\begin{aligned}
& \left\{\begin{array}{l}
\frac{\partial \mathrm{TC}}{\partial \mathrm{Q}}=0 \\
\frac{\partial \mathrm{TC}}{\partial \mathrm{~b}}=0
\end{array} \Rightarrow\right. \\
& \left\{\begin{array}{l}
Q^{*}=\sqrt{\frac{\pi}{\frac{\pi}{\hat{\pi}}}} \sqrt{\frac{2 D C_{0}}{C_{h}}-\frac{(\pi D)^{2}}{C_{h}\left(\hat{\pi}+C_{h}\right)}}=\frac{\pi D}{C_{h}}+\left(1+\frac{\hat{\pi}}{C_{h}}\right) b^{*} \quad \hat{\pi} \neq 0 \quad(2-27) \\
b^{*}=\frac{1}{\hat{\pi}+C_{h}}\left(-\pi D+\sqrt{2 D C_{0} C_{h}\left(1+\frac{C_{h}}{\hat{\pi}}\right)-\frac{C_{h}(\pi D)^{2}}{\hat{\pi}}}\right)
\end{array}\right.
\end{aligned}
$$

or

$$
b^{*}=\frac{1}{\hat{\pi}+C_{h}}\left(C_{h} Q^{*}-\pi D\right) \quad(2-29)
$$

If Eq. 2-29 gives a negative or complex value then $b=0$. However, this does not mean that an optimal value for $b^{*}$ is zero in this case, and therefore we cannot use $b^{*}=0$ in the formulas that contain $b^{*}$.

## 2-5-3 Reorder level in EOQ with backorder model

The reorder point in this model is calculated from:
$\mathrm{ROP}=\left\{\begin{array}{ll}\mathrm{DT}_{\mathrm{L}}-\mathrm{b}^{*} & \mathrm{~T}_{\mathrm{L}}<T \\ \mathrm{DT}_{\mathrm{L}}-\mathrm{b}^{*}-\mathrm{KQ}^{*}\end{array} \quad\left(\mathrm{~K}=\left[\frac{\mathrm{T}_{\mathrm{L}}}{\mathrm{T}}\right] \leq \mathrm{T}_{\mathrm{L}}\right) \quad \begin{array}{l}\mathrm{T}_{\mathrm{L}} \geq \mathrm{T}\end{array}(2-30)\right.$
Note that in this model Imax,$\overline{\mathrm{I}}$ and TC are less than the corresponding quantities in classic EOQ model, and $\mathrm{Q}^{*}>\mathrm{Q}_{\mathrm{W}}$. The following theorem is useful regarding determining the optimal value of the two-parameter function used in this model.

## Theorem 2-1 ${ }^{1}$

Second Derivative maximum-minimum test for functions of two variables. Let $f(x, y)$ be of class $C^{3}$ on an open set $U$ in $R 2$. A point ( $\mathrm{X}_{0} \cdot \mathrm{Y}_{0}$ ) is a (strict) local minimum of $f(x, y)$ provided the following three conditions hold:
(i) $\frac{\partial f}{\partial x}\left(x_{0}, y_{0}\right)=\frac{\partial f}{\partial y}\left(x_{0}, y_{0}\right)=0$
(ii) $\frac{\partial^{2} f}{\partial x^{2}}\left(x_{0}, y_{0}\right)>0$
(iii) $D=\left(\frac{\partial^{2} f}{\partial x^{2}}\right)\left(\frac{\partial^{2} f}{\partial y^{2}}\right)-\left(\frac{\partial^{2} f}{\partial x \partial y}\right)^{2}>0$ at $\left(x_{0}, y_{0}\right)$

D is called the discriminant of the Hessian. If in (ii) we have <0 instead of >0 and condition (iii) is unchanged, then we have a (strict) local maximum.

Question : what is the criterion for a point to be a global optimum of function $f$.

Answer : There is no simple answer; however if $f$ is continuous and $\nabla f(x, y)=0$ has only one answer, it is the global.

## 2-5-4 Optimal (Q) and (b) when $\widehat{\pi} \neq 0 \& \pi=0$ :

If the stockout cost per unit time for each unit is not zero ( $\widehat{\pi} \neq 0$ ) and fixed stockout cost per unit is zero $(\pi=0)$; substituting $\pi=0$ in Eq. 2-26 to2-29 yields the following results:

[^2]$Q^{*}=\sqrt{\frac{\hat{\pi}+C_{h}}{\hat{\pi}}} \sqrt{\frac{2 D_{0}}{C_{h}}} \quad b^{*}>0$
\[

$$
\begin{gathered}
b^{*}=\sqrt{\frac{2 D C_{0} C_{h}}{\widehat{\pi}\left(\hat{\pi}+C_{h}\right)}}=\sqrt{\frac{2 D C_{0}}{C_{h}}}\left(\sqrt{\frac{\hat{\pi}+C_{h}}{\hat{\pi}}}-\sqrt{\frac{\hat{\pi}}{\hat{\pi}+C_{h}}}\right) \\
=Q^{*}\left(\frac{C_{h}}{\hat{\pi}+C_{h}}\right)
\end{gathered}
$$
\]

$$
\begin{equation*}
T C^{*}=\sqrt{2 \mathrm{DC}_{\mathrm{O}} \mathrm{C}_{\mathrm{h}}} \sqrt{\frac{\hat{\pi}}{\hat{\pi}+\mathrm{C}_{\mathrm{h}}}}+\mathrm{PD}=\mathrm{C}_{\mathrm{h}} \mathrm{~s}^{*}+\mathrm{PD}=\widehat{\pi}^{*}+\mathrm{PD} \tag{2-33}
\end{equation*}
$$

$\mathrm{Q}=\mathrm{b}+\mathrm{s} \Rightarrow \mathrm{s}=\mathrm{Q}-\mathrm{b} \Rightarrow$

$$
\begin{gather*}
s^{*}=Q^{*}-b^{*}  \tag{2-33}\\
s^{*}=I_{m a x}^{*}=\sqrt{\frac{2 D C_{0}}{C_{h}}} \sqrt{\frac{\hat{\pi}}{\hat{\pi}+C_{h}}}=Q^{*} \frac{\hat{\pi}}{\hat{\pi}+C_{h}}  \tag{2-34}\\
\bar{b}^{*}=\frac{b^{* 2}}{2 Q^{*}}=\frac{Q^{*}}{2} \times\left(\frac{C_{h}}{\hat{\pi}+C_{h}}\right)^{2} \tag{2-35}
\end{gather*}
$$

Also note that in this model if $\hat{\pi} \neq 0$ and $\pi=0$; we have:

$$
\begin{align*}
& \mathrm{Q}_{\text {backorder }}^{*}=\mathrm{Q}_{\mathrm{W}} \sqrt{\frac{\hat{\pi}+\mathrm{C}_{\mathrm{h}}}{\hat{\pi}}}  \tag{2-36}\\
& \mathrm{TVC}^{*}=\mathrm{TC}_{\mathrm{W}} \sqrt{\frac{\hat{\pi}}{\hat{\pi}}}  \tag{2-3v}\\
& \mathrm{~b}_{(\pi=0)}^{*}=\frac{\mathrm{C}}{\mathrm{~h}}  \tag{2-38}\\
& \sqrt{\hat{\pi}\left(\hat{\pi}+\mathrm{C}_{\mathrm{h}}\right)}
\end{align*} \mathrm{Q}^{*} \frac{\mathrm{C}_{\mathrm{h}}}{\hat{\pi}+\mathrm{C}_{\mathrm{h}}} \quad \hat{\pi} \neq 00
$$

and if the cost of holding one unit per unit time( Ch )is largish then :
$Q^{*}=\sqrt{\frac{2 \mathrm{DC}_{0}}{\hat{\pi}}}, \quad \mathrm{TC}^{*}=\sqrt{2 \mathrm{DC}_{\mathrm{O}} \widehat{\pi}}, \mathrm{b}^{*}=\mathrm{Q}^{*}$.

## Example 2-8

An item is purchased for $\$ 10$ per unit. The order cost is $\$ 117.5$. The daily holding cost per unit is $1 \%$ of the price and the monthly demand for the item is 125 units. The lead time is 10 working days and there is 200 working days in a year. If back ordering is possible and the stockout cost per unit per day is $\$ 0.2$.

Find the optimal order quantity, maximum of inventory, maximum of stockout, reorder point, the cycle time and the annual total cost in the optimal state. Also calculate the carrying cost and the stockout cost during a cycle time.

## Solution

$$
\mathrm{I}_{\text {daily }}=0.01, \mathrm{P}=\$ 10, \mathrm{D}=125 \text { per month }, \mathrm{C}_{\mathrm{O}}=\$ 117.5, \mathrm{~T}_{\mathrm{L}}=10 \text { days }
$$

$\widehat{\pi}=\$ 0.2$ per day $\quad \pi=0$
$Q^{*}=\sqrt{\frac{\hat{\pi}+C_{h}}{\hat{\pi}}} \sqrt{\frac{2 D C_{0}}{C_{h}}}$
$\mathrm{C}_{\mathrm{h}}=\mathrm{IP}=0.01 * 10$ per day $=.01 * 10 * 365=36.5 \$$ per year
$\widehat{\pi}=0.2 * 200=40 \$$ per year
Using MATLAB:
$Q^{*}=$
$\operatorname{sqrt}((.2 * 200+36.5) /(.2 * 200)) * \operatorname{sqrt}((2 * 125 * 12$

* 117.5)/(36.5)) $\cong 136$
$b_{(\pi=0)}^{*}=Q^{*} \frac{C_{h}}{\hat{\pi}+C_{h}}=65$
The maximum inventory is:
$\mathrm{s}^{*}=\mathrm{I}_{\max }^{*}=\mathrm{Q}^{*} \frac{\hat{\pi}}{\hat{\pi}+\mathrm{C}_{\mathrm{h}}}=70$
$\mathrm{ROP}=\mathrm{DT}_{\mathrm{L}}-\mathrm{b}^{*}=\frac{125 * 12 * 10}{200}-65=10$,
$\mathrm{TC}^{*}=\mathrm{Th}^{*}+\mathrm{PD}=0.2^{*} 200^{*} 65+10^{*} 125^{*} 200=252600 \$$
$\mathrm{T}^{*}=\frac{\mathrm{Q}^{*}}{\mathrm{D}}=\frac{136}{125 \times 12}=0.09 \mathrm{yr} \rightarrow \mathrm{T}^{*}=0.09 * 200=18$ days
The carrying cost for a cycle time ( T ) is equal to $\hat{\pi} \times \mathrm{T}=\$ 3.6$, the stockout cost during T equals $\mathrm{ChT}=0.01 * 10 * 18=\$ 1.8$.

The reader should verify that $\mathrm{b}^{*}=65$ and $\mathrm{Q}^{*}=136$ satisfy theorem 2-1

## 2-2-5 Some comments on backordering

In this section some comments are provided on the backordered EOQ model. Most of these comment could be verified using the following relationships especially Eq. (I).

$$
T C(Q, b)=\frac{C_{0} D}{Q}+C_{h} \frac{(Q-b)^{2}}{2 Q}+\widehat{\pi} \frac{b^{2}}{2 Q}+\frac{\pi b D}{Q}+P D
$$

Differentiating with respect to $b \& Q$ :

$$
\begin{array}{r}
\frac{\partial \mathrm{TC}}{\partial \mathrm{~b}}=0 \Rightarrow-\mathrm{Ch}(\mathrm{Q}-\mathrm{b})+\widehat{\pi} \mathrm{b}+\pi \mathrm{D}=0 \\
\frac{\partial \mathrm{TC}}{\partial \mathrm{Q}}=0 \Rightarrow \frac{1}{Q^{2}}\left(D C_{o}+\pi D b+\frac{\hat{\pi}+C_{h}}{2} b^{2}\right)=\frac{C_{h}}{2} \Rightarrow
\end{array}
$$

$$
\begin{aligned}
\frac{1}{2} Q^{2} & =\frac{1}{C_{h}}\left(D C_{O}+\pi D b+\frac{\hat{\pi}}{2} b^{2}\right)+\frac{b^{2}}{2} \\
\frac{\partial \mathrm{TC}}{\partial \mathrm{Q}} & =0 \\
\frac{\partial \mathrm{TC}}{\partial \mathrm{~b}} & =0
\end{aligned} \Rightarrow\left(\hat{\pi}^{2}+\widehat{\pi} \mathrm{C}_{\mathrm{h}}\right) \mathrm{b}^{2}+2 \pi \hat{\pi} \mathrm{Db}+(\pi \mathrm{D})^{2}-2 \mathrm{DC}_{0} \mathrm{C}_{\mathrm{h}}=0
$$

$$
\begin{aligned}
& \mathbf{( \mathbf { l } ) \Rightarrow} \\
& b^{*}=\frac{-\pi D+\sqrt{(\pi D)^{2}+\frac{\hat{\pi}+C_{h}}{\hat{\pi}}\left(2 D C_{o} C_{h}-\pi^{2} D^{2}\right)}}{\hat{\pi}+C_{h}} \quad \hat{\pi} \neq 0
\end{aligned}
$$

or Eq. 2-28 i.e.

$$
\mathrm{b}^{*}=\frac{1}{\hat{\pi}+C_{h}}\left(-\pi D+\sqrt{2 D C_{0} C_{h}\left(1+\frac{C_{h}}{\widehat{\pi}}\right)-\frac{C_{h}(\pi D)^{2}}{\widehat{\pi}}}\right)
$$

## Comments on the model when $\widehat{\boldsymbol{\pi}}=0$ :

a)If $\boldsymbol{b}^{*}=\mathbf{0}$

As mentioned above

$$
\begin{aligned}
& \frac{\partial T C}{\partial Q}=0 \Rightarrow \frac{1}{Q^{2}}\left(D C_{o}+\pi D b+\frac{\hat{\pi}+C_{h}}{2} b^{2}\right)=\frac{C_{h}}{2} \\
& \quad \Rightarrow \frac{1}{Q^{2}}\left(D C_{o}+0+0\right)=\frac{C_{h}}{2} \Rightarrow Q^{*}=\sqrt{\frac{2 D C_{o}}{C_{h}}}=Q_{W}
\end{aligned}
$$

i.e. the model would be the classic EOQ model in which stockout is not permitted.
b) If $\boldsymbol{b}^{*}=\infty$

When $\boldsymbol{b}^{*}$ is largish it is preferred to place no order. In fact there would be no inventory system and an optimal back ordered cost of $\pi D$ is incurred.
c) If $\boldsymbol{\pi} \boldsymbol{D}=\boldsymbol{T} \boldsymbol{C}_{\boldsymbol{W}}=\sqrt{2 D C_{O} C_{h}}$ or $\pi D=C_{h} Q_{W} \quad$ or $\pi=\frac{\sqrt{2 C_{O} C_{h}}}{\sqrt{D}}$

In this case from Eq. (I) it would concluded optimal b could be any value $\geq 0$. $Q^{*}$ is dependent on the selected $b^{*}$.
d) If $\boldsymbol{\pi} \boldsymbol{D} \neq \boldsymbol{T} \boldsymbol{C}_{\boldsymbol{W}}$ and $\hat{\pi}=0$

In this case From Eq. (I) it is concluded that there is no positive solution for b . An also
if $\pi D \neq T C_{W}$ according to case f and e of this section, optimizing TC would result in either $b=0$ or $b=\infty$
e) if $\boldsymbol{\pi} \boldsymbol{D}>\boldsymbol{T} \boldsymbol{C}_{\boldsymbol{W}}=\sqrt{2 D C_{O} C_{h}}$ or $\pi D>C_{h} Q_{W}$ or $\pi>\frac{\sqrt{2 C_{O} C_{h}}}{\sqrt{D}}$
when $\widehat{\boldsymbol{\pi}}$ is very small, Eq.2-28 yields a complex number, and we have to use $\mathrm{b}=0$ and according to the following equation derived above :

$$
\begin{aligned}
& \frac{1}{Q^{2}}\left(D C_{o}+\pi D b+\frac{\hat{\pi}+C_{h}}{2} b^{2}\right)=\frac{C_{h}}{2} \\
& \mathrm{~b}=0 \Rightarrow \frac{1}{Q^{2}}\left(D C_{o}+0+0\right)=\frac{C_{h}}{2} \Rightarrow Q=Q_{W} .
\end{aligned}
$$

f) if $\pi D<T C_{W} \& \widehat{\pi}=0$
if $\hat{\pi}=0$ then $b^{*}=\infty$. Because according to Eq.2-28 or its equivalent i.e.

$$
\begin{aligned}
& b^{*}=\frac{-\pi D+\sqrt{(\pi D)^{2}+\left(1+\frac{C_{h}}{\hat{\pi}}\right)\left(2 D C_{o} C_{h}-\pi^{2} D^{2}\right)}}{\hat{\pi}+C_{h}}, \hat{\pi}=0 \Rightarrow \\
& b^{*}=\frac{-\pi D+\sqrt{(\pi D)^{2}+\left(1+\frac{C_{h}}{0}\right)\left(T C_{w}-\pi^{2} D^{2}\right)}}{0+C_{h}}=\infty
\end{aligned}
$$

This means we do not have an inventory systems.

## Some other comments

g) if $\boldsymbol{\pi}=0 \& \widehat{\boldsymbol{\pi}} \neq \mathbf{0}$ and finite

If the fixed cost of stockout is negligible and $(0<\hat{\pi}<\infty$, then in this model $b^{*}$ is always positive and it will be never zero or negative (b*>0).
h) if $\boldsymbol{\pi} \neq \mathbf{0} \& \widehat{\boldsymbol{\pi}} \neq \mathbf{0}$ and finite

In this case if Eq.2-28 return a negative $b^{*}\left(b^{*}<0\right)$, let $b=0$ and order as much as $\mathrm{Q}=\mathrm{Qw}$. note that this does not mean that the optimal values for b and Q are respectively zero and $\mathrm{Qw}_{\mathrm{w}}\left(\mathrm{b}^{*} \neq\right.$ $\mathbf{0}$ and $\mathrm{Q}^{*} \neq \mathrm{Q}_{\mathrm{w}}$ ).
i) if $\widehat{\boldsymbol{\pi}} \neq \mathbf{0}$
if $\widehat{\boldsymbol{\pi}} \neq \mathbf{0}, b^{*}$ would be finite
j) if $\widehat{\boldsymbol{\pi}} \neq \mathbf{0}$
if $\widehat{\boldsymbol{\pi}} \neq \mathbf{0}$, use Eq. $2-27$ i.e. $\boldsymbol{Q}^{*}=\sqrt{\frac{\hat{\pi}+C_{h}}{\hat{\pi}}} \sqrt{\frac{2 D C_{0}}{C_{h}}-\frac{(\pi D)^{2}}{C_{h}\left(\hat{\pi}+C_{h}\right)}}$ when $\mathrm{b}^{*}>0$, other wise when $\mathrm{b}^{*}<0$ choose the $\boldsymbol{Q}_{\boldsymbol{w}}$ as the order quantity; however it is not meant the optimal value is $\boldsymbol{Q}_{\boldsymbol{w}}$.
k) when $\mathrm{b}^{*}=0$

If Eq. 2-28 returns $b^{*}=0$, let $\boldsymbol{Q}^{*}=\boldsymbol{Q}_{\boldsymbol{w}}$ i.e the backordered model converts to classic EOQ model. However, when $\mathrm{b}=0$, and we let $\mathrm{Q}=\boldsymbol{Q}_{\boldsymbol{w}}$ if $\boldsymbol{\pi} \boldsymbol{D} \neq \boldsymbol{T} \boldsymbol{C}_{\boldsymbol{W}}$ then $\frac{\boldsymbol{\partial} \boldsymbol{C} \boldsymbol{C}}{\boldsymbol{\partial} \boldsymbol{b}} \neq \mathbf{0}$ and therefore $\mathrm{b}=0$ in this case could not be optimal:
$T C(Q, b)=\frac{C_{0} D}{Q}+C_{h} \frac{(Q-b)^{2}}{2 Q}+\widehat{\pi} \frac{b^{2}}{2 Q}+\frac{\pi b D}{Q}+P D$
$71 \quad$ Classical Topics in inventory Control

$$
\begin{aligned}
& \frac{\partial \mathrm{TC}}{\partial \mathrm{~b}}=\frac{-\mathrm{Ch}(\mathrm{Q}-\mathrm{b})+\pi \mathrm{D}+\hat{\pi} \mathrm{b}}{\mathrm{Q}} \quad \mathrm{Q}=\boldsymbol{Q}_{\boldsymbol{w}} \cdot \mathrm{b}=0 \\
& \frac{\partial \mathrm{TC}}{\partial \mathrm{~b}}=\frac{-\mathrm{Ch}\left(\boldsymbol{Q}_{w}-0\right)+\pi \mathrm{D}+0}{Q_{w}}=\frac{-\mathrm{Ch} \boldsymbol{Q}_{w}+\pi \mathrm{D}}{\boldsymbol{Q}_{w}}=\frac{-T \boldsymbol{C}_{w}+\pi \mathrm{D}}{\boldsymbol{Q}_{w}} \neq 0
\end{aligned}
$$

Therefore in this case when $\pi \mathrm{D} \neq \mathrm{TC}_{\mathrm{W}}, \mathrm{b}=0$ cannot be the optimal value for $b$.

## 2-6 On-hand inventory and on-order inventory

Since in inventory books you may encounter the terms " on-hand inventory " and " on-order inventory " and also symbols r \& $\boldsymbol{r}_{\boldsymbol{h}}$, a short description of them is followed.

A firm's inventory position consists of the on-hand inventory plus on-order inventory. On-hand inventory is the amount of stock items available to be sold. Quantity on order is the amount ordered from a supplier/vendor but not yet received. This also includes quantities of items being made in a work order. $r$ is the inventory on hand + the inventory on order and $\boldsymbol{r}_{\boldsymbol{h}}$ is the available inventory.

For example for both classic EOQ (Wilson) model and back-order model if $T_{L}<\mathrm{T}$ then $r_{h}=r$ is:

$$
\begin{aligned}
& r=r_{h}=\left\{\begin{array}{cc}
D T_{L} & \text { Wilson EOQ Model } \\
D T_{L}-b^{*} & \text { Back - ordered EQO }
\end{array} T_{L}<T\right. \\
& \text { If } \mathrm{T}_{\mathrm{L}} \geq \mathrm{T}
\end{aligned}
$$

$r=$ on-order inventory is :

$$
r_{h}=\left\{\begin{array}{cc}
D T_{L}-K Q^{*} & \text { EOQ Model } \\
D T_{L}-b^{*}-K Q^{*} \text { Back }- \text { ordered }
\end{array} \quad K=\left[\frac{T_{L}}{T}\right] \quad T_{L} \geq T \quad(2-41)\right.
$$

At the time point just before the arrival an order, the sum of onhand inventory and on-order inventory is equal to the consumption during lead time i.e. $D \times T_{L}{ }^{1}$;because $r_{h}=R O P=D T L_{L}-K Q \quad K=\left[\frac{T_{L}}{T}\right]$ is the on hand inventory $\left(r_{h}\right)$ at this point and the on-order inventory is KQ , where K is the integral part of $\frac{\mathrm{T}_{\mathrm{T}}}{\mathrm{T}}$. At point in time just after the arrival of an order quantity, $D T_{L}$ is increased by Q , then

$$
D T_{L} \leq \quad \begin{gather*}
\text { On-hand+on- }  \tag{2-43}\\
\text { order inventory }
\end{gather*} \leq \mathrm{DT}_{\mathrm{L}}+\mathrm{Q}
$$

## 2-7 EOQ Model -lost sale case

In the previous models, there was either no stockout in the system, or the stockout was backordered and later compensated. Now we would like to analyze a case in which for a time say $\mathrm{T}_{2}$ (see Fig 2-10 )the demand is not satisfied and is lost (or is backordered without compensation). In this case the aim is to find the optimal value of $\mathrm{T}_{2}$ and Q .

[^3]

Fig. 2-10 Lost-sale Model
Now considering an inventory system in which there is stockout, but is not compensated and is lost, let us calculate its total $\operatorname{cost}(\mathrm{TC})$, which is actually an average annual cost.

Fig. 2-11 Maximum stockout and inventory in lost -sale model

$$
T=T_{1}+T_{2} \Rightarrow T=\frac{Q}{D}+T_{2}=\frac{Q+D T_{2}}{D},
$$

Number of annual cycles (m) and the average annual inventory $(\bar{I})$ are:
$m=\frac{1}{T}=\frac{D}{Q+D T_{2}}$,
$\bar{I}=\frac{\mathrm{m} \times \text { area of one triangle in Fig } 2-11}{1 \text { year }}=\frac{1}{T}\left(\frac{1}{2} Q \frac{Q}{D}\right) \Rightarrow$
$\bar{I}=\frac{D}{Q+D T_{2}}\left(\frac{1}{2} Q \frac{Q}{D}\right)=\frac{1}{2} \times \frac{Q^{2}}{Q+D T_{2}}$.
If the annual carrying cost of unit product is $\mathrm{C}_{\mathrm{h}}$ and the cycle time in year is T . then
annual average carrying cost in the system $=\mathrm{C}_{\mathrm{h}} \overline{\mathrm{I}}$,
average carrying cost per cycle time $=C_{h} \overline{\mathrm{I}} \mathrm{T}=\frac{1}{2} \frac{\mathrm{Q}^{2}}{\mathrm{D}} \mathrm{C}_{\mathrm{h}}$.

Stockout cost per cycle $=\pi D T_{2}$
Number of cycles per year $=\frac{D}{Q+\mathrm{DT}_{2}}$,
Annual stockout cost $=\pi \mathrm{DT}_{2}\left(\frac{\mathrm{D}}{\mathrm{Q}+\mathrm{DT}_{2}}\right)$.
$\mathrm{TC}=\mathrm{C}_{\mathrm{O}}\left(\frac{1}{\mathrm{~T}}\right)+\mathrm{C}_{\mathrm{h}}(\overline{\mathrm{I}})+\pi \mathrm{DT}_{2}\left(\frac{1}{\mathrm{~T}}\right)$,

$$
\mathrm{TC}=\mathrm{C}_{\mathrm{O}}\left(\frac{\mathrm{D}}{\mathrm{Q}+\mathrm{DT}_{2}}\right)+\frac{\mathrm{C}_{\mathrm{h}}}{2}\left(\frac{\mathrm{Q}^{2}}{\mathrm{Q}+\mathrm{DT}_{2}}\right)+\pi \mathrm{DT}_{2}\left(\frac{\mathrm{D}}{\mathrm{Q}+\mathrm{DT}_{2}}\right) .
$$

TC is a bivariate function, to find its optimum, its partial derivatives are set equal to zero:

$$
\begin{align*}
& \left\{\begin{array}{l}
\frac{\partial T C}{\partial Q}=0 \Rightarrow-C_{O} D+\frac{C_{h} Q^{2}}{2}-\pi D^{2} T_{2}+C_{h} Q D T_{2}=0 \\
\frac{\partial T C}{\partial T_{2}}=0 \Rightarrow \pi D=\frac{C_{O} D}{Q}+C_{h} \frac{Q}{2} \quad 0<T_{2}<\infty, 0<Q<\infty
\end{array}\right.  \tag{I}\\
& (I I) \Longrightarrow \pi D=\frac{2 C_{O} D+C_{h} Q^{2}}{2 Q} \Rightarrow C_{h} Q^{2}-2 \pi D Q+2 C_{O} D=0 \Rightarrow \tag{II}
\end{align*}
$$

$$
\begin{gathered}
Q=\frac{\pi D \pm \sqrt{(\pi D)^{2}-2 C_{O} D C_{h}}}{C_{h}}=Q=\frac{\pi D \pm \sqrt{(\pi D)^{2}-T C_{w}^{2}}}{C_{h}} \Rightarrow \\
Q=\frac{\pi D}{C_{h}} \pm \sqrt{\left(\frac{\pi D}{C_{h}}\right)^{2}-\frac{2 C_{o} D}{C_{h}}} \quad(I I I)
\end{gathered}
$$

Now let us talk about the optimal value of Q and $\mathrm{T}_{2}$ when the result of the radical in Eq.(III) is a complex number, zero, a real number or equivalently $\pi D$ is less than, equal or greater than $T C_{W}=\sqrt{2 C_{O} D C_{h}}$ in this model.

The value of Q*

1) $\pi D<T C_{W}$

In Eq. (III), if $\pi D<T C_{W}$, then there would be no real answer for Q there is no inventory system i.e. $\mathrm{Q}=0$. Later it will be shown that $T_{2}^{*}=\infty$. Substituting $T_{2}^{*}=+\infty \& Q=0$ in annual average cost i.e.

$$
T C=C_{O}\left(\frac{D}{Q+D T_{2}}\right)+\frac{C_{h}}{2}\left(\frac{Q^{2}}{Q+D T_{2}}\right)+\pi D\left(\frac{D}{\frac{Q}{T_{2}}+D}\right)
$$

results $T C=\pi D$. Note there in no income in this case.
2) $\boldsymbol{\pi D}=\boldsymbol{T} \boldsymbol{C}_{\boldsymbol{W}}$

Eq. (III), If $\pi \mathrm{D}=\mathrm{TC}_{\mathrm{W}}$, Eq. (III) has double root of $Q^{*}=\frac{\pi D}{c_{h}}$. It will be shown that $\mathrm{T}_{2}$ could be any positive number.
3) $\pi D>T C_{W}$

Although Eq. III gives 2 answers for Q ; but It will be shown that $T_{2}^{*}=0$ and the order quantity is necessarily equal to $\mathrm{Q}_{\mathrm{W}}$

The value of $\mathrm{T}^{*}$
There is a discussion about the optimum value of the cycle time(T) in some books including Bazargan (2021). The summary of the discussion is:

1) $\boldsymbol{\pi} \boldsymbol{D}<\boldsymbol{T} \boldsymbol{C}_{\boldsymbol{W}}$

It is proved that $T_{2}=\infty$
2) $\boldsymbol{\pi} \boldsymbol{D}=\boldsymbol{T} \boldsymbol{C}_{\boldsymbol{W}}$

It is proved $T_{2}$ could be any positive number.
3) $\pi D>T C_{W}$

In this case $\quad T_{2}^{*}=0$
We summary the above discussion is as follows:

Case 1) $\boldsymbol{\pi} \boldsymbol{D}<\boldsymbol{T} \boldsymbol{C}_{\boldsymbol{W}}$

In this case it is proved that $T_{2}=\infty \& Q^{*}=0$ i.e. there is no inventory system.

Case 2) $\boldsymbol{\pi} \boldsymbol{D}=\boldsymbol{T} \boldsymbol{C}_{\boldsymbol{W}}$
In this case it is proved $Q^{*}=\frac{\pi D}{C_{h}}$ and $T_{2}$ could be any positive number.

Case 3) $\boldsymbol{\pi} \boldsymbol{D}>\boldsymbol{T} \boldsymbol{C}_{\boldsymbol{W}}$
In this case $T_{2}^{*}=0 \& Q^{*}=\mathrm{Q}_{\mathrm{W}}$ i.e. the model converts to the classic model.

Note that:
-the product $\pi \times D$ is the cost of lost sale for the whole demand.
-the case in which $\pi D<T C_{W}$ is similar to one of the cases in backordered classic EOQ model where $\pi D<T C_{W} \quad \& \hat{\pi}=0$ and consequently we did not an inventory system.
-Some researches has been done to combine backordering with lost sales in EOQ model.
77 Classical Topics in inventory Control

## Example 2-9

Consider an EOQ model where lost sale is possible and
$C_{h}=0.8$ per unit per year, $C_{O}=0.2, T_{L}=0.1$ year,$\pi=0.2$
Deter mine which the above cases is applicable here? And what should be done?

## Solution

$\pi D=0.2 \times 104000=20800, T C_{W}=\sqrt{2 \times 104000 \times 0.2 \times 0.8}=182.4$
$\pi D=20800>T C_{W}=182.4$
Then Case 3 is applicable here $: \mathrm{T}_{2}^{*}=0$ and $Q^{*}=Q_{W}=228$.

## Quantity Discount Models

The preceding models have assumed that the unit price of an item is the same regardless of the quantity in the batch; however, It is common for suppliers to give price discounts when order quantities are high. When discounts are factored into the calculation, the economic order quantity may change. In this section we deal with two types of discount models in inventory systems:
Discount Model $\left\{\begin{array}{l}\text { Total Discount Model }\left\{\begin{array}{l}\mathrm{C}_{\mathrm{h}} \text { changing with price } \\ \text { Fixed } C_{h}\end{array}\right. \\ \text { Incremental Discount Model }\end{array}\right.$

## 2-8 Total Discount Model

In this type of discount model, the unit price changes with order quantity in a manner similar to what the following table shows:

| Price | Order quantity $(\mathrm{Q})$ |
| :--- | :---: |
| $\mathrm{P} 1=\max (\mathrm{Pi})$ | $\mathrm{Q}<\mathrm{Q} 1$ |
| P 2 | $\mathrm{Q} 1 \leq \mathrm{Q}<\mathrm{Q} 2$ |
| P 3 | $\mathrm{Q} 2 \leq \mathrm{Q}<\mathrm{Q} 3$ |
| $\mathrm{P} 4=\min (\mathrm{Pi})$ | $\mathrm{Q} \geq \mathrm{Q} 3$ |

Chapter 2 Deterministic Models
Let $\mathrm{R}(\mathrm{Q})$ denote the purchase cost. In this type $\mathrm{R}(\mathrm{Q})=\mathrm{PQ}$. Figure 2-13 shows the function $R(Q)$ in terms of $Q . Q_{1}, Q_{2, \ldots}$ are called price break points.

Fig. 2-12 Purchase cost of an order in a

Total discount model with 2 break points
Remember that $T C=C_{O} \frac{D}{Q}+\frac{I P}{2} Q+P D$ gives, total cost for each price. The graphical description of the components of the total cost is shown in figure 2-13

Fig. 2-13 The components of the total cost for one price
This model has two types i.e. either Ch changes with unit price or does not change with price.

## 2-8-1 Quantity Discount Model -Ch variable

If Ch changes with unit price and the price is similar to those given in the table above, the carrying cost reduces as the order quantity increases. The optimal order quantity in this type of the model could be determined using an algorithm described below.

## 2-8-1-1 The algorithm for finding optimal Q - <br> Case 1: $\mathrm{C}_{\mathrm{h}}$ variable

Figure 2-14 shows the curves of total cost for an all-unitdiscount model where there are 3 price break points.

Fig.2-14 Total cost curves for a total- discount model
The steps of the algorithm of finding optimal order quantity $\mathrm{Q}^{*}$ is (Dilworth,1989, page 263):

## Step 1:

Calculate $Q_{W}=\sqrt{\frac{2 D C_{O}}{I P}}$ for $\mathrm{P}=\min \left(\mathrm{P}_{\mathrm{i}}\right) . \quad$ If $Q_{W}$ is feasible i.e. satisfies the corresponding interval of this price, it is the answer to our problem, otherwise go to step2.

## Step 2:

Calculate $Q_{W}$ for the immediate higher price, if it is feasible calculate annual total cost $T C=\frac{C_{O} D}{Q}+\frac{C_{h} Q}{2}+P D$ for this price and the break points which are greater than it; the value with least TC is the optimal Q. Other- wise if the $Q_{W}$ is not feasible go to step 3 .

## Step 3

Repeat Step 2 until a feasible $Q_{W}$ is obtained.
The reorder point is $R O P=D T_{L}$ for $T_{L}<T$.

## Example 2-10

The annual demand for a product is 2500 , the yearly carrying cost of unit product is $\$ 0.10$ and the order cost is $\$ 100$. The supplier offers discount according the following Table:

| Ro | Q |  |
| :--- | :--- | :--- |
| 1 | $0 \leq \mathrm{Q}<500$ | 5 |
| 2 | $500 \leq \mathrm{Q}<2500$ | 4.75 |
| 3 | $2500 \leq \mathrm{Q}<5000$ | 4.6 |
| 4 | $\mathrm{Q} \geq 5000$ | 4.5 |

Find the optimal order quantity, the cycle time $\mathrm{T}^{*}$. There are 300 working days in a year and the lead time in 10 working days.

## Solution

The minimum price is $4.5 ; Q_{W}=\sqrt{\frac{2 \times 2500 \times 100}{0.1 \times 4.5}} \cong 1054$.
The amount does not satisfy the corresponding interval i.e. $\mathrm{Q} \geq 5000$.

For the price $\mathrm{P}=4.6 \quad Q_{w_{P}=4.6} \cong 1043$ is not feasible;
For $\mathrm{P}=4.75 \quad Q_{w_{P}=4.6} \cong 1026$ is feasible.
We calculate TC for this value and the break points which are greater:
$T C(Q=1026, P=4.75)=\frac{C_{O} D}{Q}+\frac{C_{h} Q}{2}+P D=12362$
$T C(Q=2500, P=4.6)=12175$
$T C(Q=5000, P=4.5)=12425$
There fore $Q^{*}=2500 . \mathrm{T}^{*}=\frac{Q^{*}}{D}=\frac{2500}{2500}=1$
There is no reorder point in 1 year

## 2-8-2 Quantity Discount Model-Case II: $\mathrm{C}_{\mathrm{h}}$ Fixed

This type of discount model is similar to the previous one described in Sec 2-8-1 except that the carrying cost per unit product $\left(\mathrm{C}_{\mathrm{h}}\right)$ does not depend on the price and is a fixed value. In this type $\mathrm{Q}_{\mathrm{w}}$ is the same for all intervals. If $\mathrm{Q}_{\mathrm{w}}$ satisfies the interval related to the minimum price, it is the optimal order quantity; otherwise calculate the total cost for $\mathrm{Q}_{\mathrm{w}}$ and the price break points greater than it; the value with less TC is the answer.

## Example 2-11

A supplier offers all- unit discount according to the following table for a product whose annual $\mathrm{C}_{\mathrm{h}}$ is $\$ 100, \mathrm{C}_{\mathrm{o}}=\$ 100$ and annual $D=1000$. Find the
optimal order quantity.

| Q | $0-99$ | $100-199$ | 200 and more |
| :--- | :--- | :--- | :--- |
| price | 500 | 400 | 300 |

## Solution

The curves of total cost for the 3 prices are shown below.

$\mathrm{Q}_{\mathrm{w}}=\sqrt{\frac{2 D C_{0}}{C_{h}}}=\sqrt{\frac{2 \times 1000 \times 100 \times 12}{100}}=154.9 \approx 155$
$T C\left(Q_{W}=155, P=400\right)=\sqrt{2 \times 12000 \times 100 \times 100}+400 \times 12000=$ 4815492.
$\mathrm{Q}_{\mathrm{w}}$ does not satisfy the interval related to the minimum price i.e. (200 and more). Therefore the total cost for the price break points more than $\mathrm{Q}_{\mathrm{w}}$ has to be calculated.

$$
\begin{aligned}
T C(Q, P) & =C_{O} \frac{D}{Q}+C_{h} \frac{Q}{2}+P D \\
T C(Q & =200, P=300)=3616000, \text { therefore } \mathrm{Q}^{*}=200 .
\end{aligned}
$$

## 2-9 Converse of Discount Model (rate increase with quantity increase)

Here the purpose is to deal with the cases where a rate and the holding cost increases as the quantity increases. An example follows:

Suppose in a deterministic inventory system, stockout is not permitted and the rent of a warehouse is to paid as well as $\mathrm{C}_{\mathrm{h}}=\mathrm{IP}$ for each unit hold in warehouse. The rent is not included in the holding cost $\mathrm{C}_{\mathrm{h}}$ and changes with the increase of order quantity. The total cost(TC) component of annual rent cost is determined based on the maximum inventory. Now we would like to calculate the economic order quantity. If
the annual rent per unit product is $h_{1}$, then:

$$
\begin{gathered}
\mathrm{TC}(\mathrm{Q})=\mathrm{PD}+\frac{C_{O} \mathrm{D}}{\mathrm{Q}}+I P \frac{\mathrm{Q}}{2}+h_{1} \mathrm{Q} \quad \frac{\mathrm{dTC}}{\mathrm{dQ}}=0 \quad \Rightarrow \\
Q^{*}=\sqrt{\frac{2 D C_{O}}{2 h_{1}+I P}} \quad(2-47)
\end{gathered}
$$

The algorithm for determining the economic order quantity is similar to the previous algorithm described in Sec 2-8-1-1 and is illustrated below. In this model the break point located at left side of $Q^{*}$ could also be the answer.

## Example 2-12

The annual demand for a product is 10000 , the order cost is $\$ 64$, the unit price is $\$ 4$ the annual cost of holding 1 unit product in warehouse is $\$ 0.25$.

Find the economic order quantity. No stockout is permitted and as well as this cost, for each unit product a separate annual $\operatorname{cost}\left(\mathrm{h}_{1}\right)$ has to be paid for holding the products in warehouse. The annual rent cost
per unit product depends on the quantity ordered $(\mathrm{Q})$ as given in the following table:

| Q | $0 \leq \mathrm{Q}<500$ | $500 \leq \mathrm{Q}<750$ | $750 \&$ more |
| :--- | :---: | :---: | :--- |
| $\mathrm{h}_{1}$ | 1 | 1.5 | 2 |

## Solution

Starting with the least rate $\mathrm{h}_{1}=1$
$h_{1}=1 \rightarrow Q_{1}=\sqrt{\frac{2 D C_{O}}{2 h_{1}+I P}}=\sqrt{\frac{2 \times 10000 \times 64}{2 \times 1+0.25 \times 4}} \cong 653$ infeasible,
$\mathrm{Q}_{1}$ is not reasible because it does not satisfy $0<\mathrm{Q} \leq 500$.
$h_{1}=1.5 \rightarrow \mathrm{Q}_{2}=\sqrt{\frac{2 \times 64 \times 10000}{2 \times 1.5+0.25 \times 4}} \cong 566 \quad$ feasible
$h_{1}=2 \rightarrow \mathrm{Q}_{3}=\sqrt{\frac{2 \times 64 \times 10000}{2 \times 2+0.25 \times 4}} \cong 506$ infeasible

Now we compare the total cost feasible $Q=566$ and the break points $500 \& 750$.

$$
\begin{aligned}
\mathrm{TC}(\mathrm{Q})=\mathrm{PD} & +\frac{C_{O} \mathrm{D}}{\mathrm{Q}}+I P \frac{\mathrm{Q}}{2}+h_{1} \mathrm{Q} \\
\mathrm{TC}(\mathrm{Q}=566) & =4 \times 10000+64 \times \frac{10000}{566}+0.25 \times 4 \times\left(\frac{566}{2}\right) \\
& +1.5 \times(566) \cong 42263 \\
\mathrm{TC}(\mathrm{Q}=500) & =4 \times 10000+64 \times \frac{10000}{500}+\frac{0}{25} \times 4 \times\left(\frac{500}{2}\right)+1.5 \\
& \times(500)=42280
\end{aligned}
$$

$\mathrm{TC}(\mathrm{Q}=750)=4 \times 10000+64 \times \frac{10000}{750}+0.25 \times 4 \times\left(\frac{750}{2}\right)+$ $2 \times(750)=42728$.

The minimum TC belongs to $\mathrm{Q}=566$; then it is the optimum.
Before dealing with another type of discount model, note that

$$
\begin{equation*}
P D=\frac{D}{Q}(\mathrm{PQ})=m \times \mathrm{R}(\mathrm{Q}) \tag{2-48}
\end{equation*}
$$

Where
$m=\frac{1}{T}=\frac{D}{Q}:$ is the number of orders per unit time (year, $\ldots$ ),
$R(Q)=P Q$ is the purchase cost per order.
2-10 Incremental discount model
In all-unit discount model, the reduced price is valid for each unit in the order quantity, whereas in this variation of discount models that is called incremental discount, only the quantity exceeding the price break quantity is available at lower price. The goal is to determine the economic order quantity and the optimal order point with minimizing costs.

## Purchase cost of order quantity $\mathbf{Q}$

In this model the following recursive relationship is used to calculate the amount of money for buying the order quantity $\mathrm{Q} ., \mathrm{R}(\mathrm{Q})$ is given by the following relationship and show in Fig 2-15.
purchase cost per order $=$
$R(Q)$
$=\left\{\begin{array}{l}R\left(q_{j}\right)+\left(P_{j}\right)\left(Q-q_{j}\right), \quad q_{j}<Q \leq q_{j+1} \quad j=0,1,2, \ldots, n \\ \left(P_{0}\right)(Q) \quad \mathrm{q}_{0}<Q \leq \mathrm{q}_{1}\end{array}\right.$
$R\left(q_{0}\right)=0 \quad, q_{0}=0 \quad, q_{n+1}=\infty$
$R\left(q_{j}\right)$ is the purchase cost of quantity $q_{j}$.

Fig. 2-15 Purchase cost of order quantity Q

## 2-10 Incremental Discount Model

Let $\mathrm{TC}_{\mathrm{j}}(\mathrm{Q})$ denote the total cost of order quantity Q when $\mathrm{q}_{\mathrm{j}}<\mathrm{Q} \leq$ $\mathrm{q}_{\mathrm{j}+1}$. Using the relationship $T C=C_{O} \frac{D}{Q}+\frac{I P}{2} Q+P D$ we could write:

$$
\begin{aligned}
T C_{j}(Q)=C_{O} & \frac{D}{Q}+\frac{I}{2} R(Q)+\frac{D}{Q} R(Q) \quad \Rightarrow \\
T C_{j}(Q)=C_{O} & \frac{D}{Q}+\frac{I}{2}\left[R\left(q_{j}\right)+P_{j} Q-P_{j} q_{j}\right] \\
& +\frac{D}{Q}\left[R\left(q_{j}\right)+P_{j} Q-P_{j} q_{j}\right]
\end{aligned} \Rightarrow
$$

$$
\Rightarrow
$$

$$
T C_{j}(Q)=\frac{D}{Q}\left[C_{O}+R\left(q_{j}\right)+P_{j} Q-P_{j} q_{j}\right]+\frac{I}{2}\left[R\left(q_{j}\right)+P_{j} Q-P_{j} q_{j}\right]
$$

$$
T C_{j}(Q)=\frac{D}{Q}\left[C_{O}+R\left(q_{j}\right)-P_{j} q_{j}\right]+\frac{I}{2}\left[P_{j} Q+R\left(q_{j}\right)-P_{j} q_{j}\right]+P_{j} D
$$

$$
q_{j}<Q \leq q_{j}+1 \quad j=0,1,2, \ldots, n
$$

And therefore:

$$
\frac{d T C_{j}(Q)}{d Q}=0 \Rightarrow Q_{j}^{*}=\sqrt{\frac{2 D\left[C_{o}+R\left(q_{j}\right)-P_{j} q_{j}\right]}{I P_{j}}} \quad j=0,1,2, \ldots, n .
$$

Plotting the $T C_{j}(Q)$ for $j=0,1,2, \ldots$ results in a figure such as Fig. 2-16

Fig. 2-16 Total Cost in incremental discount model

## 2-10-1 The algorithm for finding optimal $Q$ - incremental model

The following steps determine the order quantity.
Step1: Calculate $R(Q)$ for all break points:

$$
\begin{align*}
& q_{0}=0, \quad R\left(q_{0}\right)=0 \quad R\left(q_{1}\right)=P_{0} q_{1} \\
& R\left(q_{j+1}\right)=R\left(q_{j}\right)+\left(P_{j}\right)\left(q_{j+1}-q_{j}\right), \quad j=0,1,2, \ldots, n
\end{align*}
$$

Step2: Calculate $Q_{j}^{*}=\sqrt{\frac{2 D\left[C_{O}+R\left(q_{j}\right)-P_{j} q_{j}\right]}{I P_{j}}} \quad(2-50)$,
for $j=0,1,2, \ldots, n, \quad$ and determine which of them are feasible.

## Step3:

Calculate the total cost for the feasible $Q_{j}^{*}{ }^{\prime} s$ using the following relationship:

$$
\begin{gather*}
\operatorname{TC}\left(Q_{j}^{*}\right)=\frac{D}{Q_{j}^{*}}\left[C_{O}+R\left(q_{j}\right)-P_{j} q_{j}\right]+\frac{I}{2}\left[P_{j} Q_{j}^{*}+R\left(q_{j}\right)-P_{j} q_{j}\right]+P_{j} D \\
q_{j}<Q_{j}^{*} \leq q_{j+1} \tag{2-51}
\end{gather*}
$$

The feasible $Q_{j}^{*}$ with least total cost is the optimum.

## Note:

It could be proved that a break point $q_{j}$ could not be the local or global optimum of the total cost curves shown in Fig 2-16.

## Example 2-13

The annual demand for a product is $\mathrm{D}=2500$, annual $\mathrm{I}=0.1$ and the order cost is $\$ 100$. Find the optimal order quantity if the price per unit is as follows:

| $\mathrm{P}_{\mathrm{j}}$ | Q | comments |
| :--- | :--- | :--- |
| 5 | $\mathrm{q}_{0}=0, \mathrm{q}_{1}=500$ | for the 1 st 500 units |
| 4.75 | $\mathrm{q}_{1}=500, \mathrm{q}_{2}=2500$ | for $501,502, \ldots 2500$ |
| 4.6 | $\mathrm{q}_{2}=2500, \mathrm{q}_{3}=5000$ | for2501,2502, $\ldots 5000$ |
| 4.5 | Quantities exceeding <br> $\mathrm{q}_{3}=5000$ | for $5001 ، 5002 \iota .$. |

## Solution

Step 1: Calculation of $\mathrm{R}(\mathrm{Q})$ for break points $q_{j}$ :

$$
\begin{aligned}
& R\left(q_{j+1}\right)=R\left(q_{j}\right)+P_{j}\left(q_{j+1}-q_{j}\right) \\
& R\left(q_{0}\right)=0 \\
& R\left(q_{1}\right)=R\left(q_{0}\right)+P_{0} q_{1}=0+5(500-0)=2500 \\
& R\left(q_{2}\right)=R\left(q_{1}\right)+P_{1}\left(q_{2}-q_{1}\right)=2500+4.75(2500-500) \\
& \quad=12000 \\
& R\left(q_{3}\right)=R\left(q_{2}\right)+P_{2}\left(q_{3}-q_{2}\right)=12000+4.6(5000-2500) \\
& \quad=23500
\end{aligned}
$$

## Step 2:

$Q_{0}^{*}=\sqrt{\frac{2 D\left[C_{O}+R\left(q_{0}\right)-P_{0} q_{0}\right]}{I P_{j}}}=\sqrt{\frac{2 * 2500[100+0-5 \times 0]}{0.1 \times 5}}=1000$ infeasible
$Q_{1}^{*}=\sqrt{\frac{2 D\left[C_{O}+R\left(q_{1}\right)-P_{1} q_{1}\right]}{I P_{j}}}=\sqrt{\frac{2 * 2500[100+2500-4.75 \times 500]}{0.1 \times 4.75}}=1539$
feasible
$Q_{2}^{*}=\sqrt{\frac{2 D\left[C_{O}+R\left(q_{2}\right)-P_{2} q_{2}\right]}{I P_{j}}}=\sqrt{\frac{2 * 2500[100+12000-4.6 \times 2500]}{(0.1)(4.6)}}=$
2554 feasible
$Q_{3}^{*}=\sqrt{\frac{2 * 2500(100+23500-4.5 \times 5000)}{(0.1)(4.5)}}=3496 \quad$ infeasible

## Step 3:

Calculation the total cost of feasible values $Q_{1}^{*} \& Q_{2}^{*}$ obtained in step 2

$$
\begin{aligned}
& T C\left(Q_{1}^{*}\right)=\frac{D}{Q_{1}^{*}}\left[C_{O}+R\left(q_{1}\right)-P_{1} q_{1}\right]+\frac{I}{2}\left[P_{1} Q_{1}^{*}+R\left(q_{1}\right)-P_{1} q_{1}\right]+P_{1} D \\
& \quad T C\left(Q_{1}^{*}=1539\right)=\frac{2500}{1539}[100+2500-4.75 * 500]+\frac{0.1}{2}[4.75 * 1539+2500- \\
& 4.75 * 500]+4.75 * 2500
\end{aligned}
$$

$$
\begin{aligned}
& T C\left(Q_{2}^{*}\right)=\frac{D}{Q_{2}^{*}}\left[C_{O}+R\left(q_{2}\right)-P_{2} q_{2}\right]+\frac{I}{2}\left[P_{2} Q_{2}^{*}+R\left(q_{2}\right)-P_{2} q_{2}\right]+P_{2} D \\
& T C\left(Q_{2}^{*}=2554\right)=\frac{2500}{2554}[100+12000-4.6 * 2500] \\
&+\frac{0.1}{2}[4.6 * 2554+12000-4.6 * 2500]+4.6 * 2500
\end{aligned}
$$

$$
T C\left(Q_{2}^{*}=2554\right)=12700
$$

$$
T C\left(Q_{1}^{*}=1539\right)<T C\left(Q_{2}^{*}=2554\right) \Rightarrow Q^{*}=Q_{1}^{*}=1539
$$

## Example 2-14

Calculate the purchase cost per unit product for $q_{j}<Q \leq q_{j+1}$.

## Solution

The purchase cost of Q units in $\mathrm{q}_{\mathrm{j}}<Q \leq \mathrm{q}_{\mathrm{j}+1}$ is:

$$
\begin{aligned}
& R(Q)=R\left(q_{j}\right)+\left(P_{j}\right)\left(Q-q_{j}\right)= \\
& \mathrm{P}_{\mathrm{j}}\left(\mathrm{Q}-\mathrm{q}_{\mathrm{j}}\right)+\sum_{\mathrm{i}=1}^{j} \mathrm{P}_{\mathrm{i}-1}\left(\mathrm{q}_{\mathrm{j}}-\mathrm{q}_{\mathrm{j}-1}\right) \Rightarrow
\end{aligned}
$$

$\bar{P}_{\mathrm{j}}$, The cost per unit is:
$=\bar{P}_{\mathrm{j}}=\frac{R(Q)}{Q}=\mathrm{P}_{\mathrm{j}}\left(\frac{\mathrm{Q}-\mathrm{q}_{\mathrm{j}}}{\mathrm{Q}}\right)+\sum_{\mathrm{i}=1}^{j} \mathrm{P}_{\mathrm{i}-1}\left(\frac{\mathrm{q}_{\mathrm{j}}-\mathrm{q}_{\mathrm{j}-1}}{\mathrm{Q}}\right)$

## The inventory models for price change

A number of inventory models have been proposed to gain insight into the relationship between price changes including temporary
discounts, increase of price and order policy. Two models of these kinds are described below.

## 2-11 EOQ Model with sale price(temporary discount) ${ }^{1}$

Suppose a supplier discounts the unit price of one of his goods during a limited time in a regular replenishment period. The customer can buy once, as much as he wants with a temporary special reduction of price $d$ per unit.

The aim is to take the advantage of the short-lived discount and determine the optimum size of a special order. Consider Fig. 2-17. At point there is 2 options : 1) To continue ordering the regular quantity Q ; the first lot arrives with unit price p -d.

2) To place a special order of size $Q^{\prime}$ with unit price $p-d$; when this amount is consumed, lots of regular size Q and unit price p arrive from point $\mathrm{C} . \mathrm{T}^{\prime}=\frac{\mathrm{Q}^{\prime}}{D}$ is the time needed to consume the special order. Saving in this model is equal to the difference between the cost during the time period T' with and without the special order Q'. Now we would like to find that value of $\mathrm{Q}^{\prime}$ which maximize the saving.

[^4]Let $\mathrm{K}^{\prime}$ denote the average cost during period $\mathrm{T}^{\prime}$ if a special order of size $\mathrm{Q}^{\prime}$ is placed. $\mathrm{K}^{\prime}$ has three components i.e. order cost $\left(C_{o}\right)$, purchase cost : $(P-d) Q^{\prime}$ and average carrying cost during the time period which is derived as following using Fig. 2-17:

Average inventory during time $\mathrm{T}^{\prime}=\frac{\frac{1}{2} Q^{\prime} \mathrm{T}^{\prime}}{\mathrm{T}^{\prime}}=\frac{1}{2} Q^{\prime}$
$C_{h}$ is the holding cost of one unit product in 1 year
$C_{h} \mathrm{~T}^{\prime}$ is the holding cost of one unit product during time period $\mathrm{T}^{\prime}=$
$I(P-d) \times \frac{\left(Q^{\prime}\right)}{D}$
average carrying cost during the time period

$$
\begin{gather*}
\mathrm{T}^{\prime}=I(P-d) \times \frac{\left(Q^{\prime}\right)}{D} \times \frac{1}{2} Q^{\prime}=I(P-d) \frac{\left(Q^{\prime}\right)^{2}}{2 D} . \text { then : } \\
K^{\prime}=C_{O}+I(P-d) \frac{\left(Q^{\prime}\right)^{2}}{2 D}+(P-d) Q^{\prime} \tag{2-52}
\end{gather*}
$$

Let K denote the average cost during period $\mathrm{T}^{\prime}$ if a special order of size Q ' is not placed. Noting that only the unit price of the first order is $P-d$ and that of the other orders is p , we could write:

$$
K=C_{O} \frac{Q^{\prime}}{Q}+\left\{\begin{array}{c}
I(P-d) \frac{Q}{2} \overbrace{\left(\frac{Q}{D}\right)}^{\text {time } A B} \\
+I P \frac{Q}{2} \underbrace{\left(\frac{Q^{\prime}-Q}{D}\right)}_{\text {time } B C}
\end{array}+(P-d) Q+\left(Q^{\prime}-Q\right) P .\right.
$$

To find the optimal one-time special order ( $\mathrm{Q}^{\prime}$ ), the saving i.e. the difference in the above 2 cost must be maximized:
$G=K-K^{\prime}=$
$d \times\left(Q^{\prime}-Q\right)-\frac{d I Q^{2}-I P Q Q^{\prime}}{2 D}-\frac{I(P-d) Q^{\prime 2}}{2 D}+\frac{C_{O} Q^{\prime}}{Q}-C_{O}(2-52)$
where $\mathrm{Q}=\mathrm{Q}_{\mathrm{W}}$.
The second derivative of G with respect to $\mathrm{Q}^{\prime}$ is $-\frac{I(P-d)}{D}<0$; then G has a maximum. To find the optimal $\mathrm{Q}^{\prime}$, the first derivative is set equal to zero(tersine, 1994 page 116):

$$
\begin{aligned}
& \frac{d G}{d Q^{\prime}}=0 \Rightarrow d+\frac{I P Q}{2 D}-\frac{I(P-d) Q^{\prime}}{D}+\frac{C_{O}}{Q}=0 \\
& \quad \Rightarrow Q^{\prime *}=\frac{2 \mathrm{dDQ}+\mathrm{IPQ}^{2}+2 \mathrm{C}_{0} \mathrm{D}}{\mathrm{IQ}(\mathrm{P}-\mathrm{d})}=\frac{2 \mathrm{dDQ}+\mathrm{IPQ}^{2}+\mathrm{IPQ}^{2}}{\mathrm{IQ}(\mathrm{P}-\mathrm{d})}
\end{aligned}
$$

The above formula is valid when the stock position is zero ( $\mathrm{q}=0$ ) on the expiration date:

$$
\begin{equation*}
\mathrm{Q}^{\prime *}=\frac{\mathrm{dD}}{\mathrm{I}(\mathrm{P}-\mathrm{d})}+\frac{\mathrm{PQ}}{\mathrm{P}-\mathrm{d}}=\frac{\mathrm{dD}+\mathrm{IPQ}}{\mathrm{I}(\mathrm{P}-\mathrm{d})} \quad \mathrm{q}=0 \tag{2-53}
\end{equation*}
$$

The saving due to placing this amount of order is((Tersine, 1994 page 116) :

$$
\begin{equation*}
G^{*}=\frac{C_{o}(P-d)}{P}\left(\frac{Q^{\prime *}}{Q_{W}}-1\right)^{2} \quad q=0 \tag{2-54}
\end{equation*}
$$

If the special order must be placed before the regular replenishment time and the stock position is q units on the expiration date, the optimizing formulations are(Tersine, 1994, page116):

$$
\begin{equation*}
\mathrm{Q}^{\prime *}=\frac{\mathrm{dD}+\mathrm{IPQ}_{\mathrm{W}}}{\mathrm{I}(\mathrm{P}-\mathrm{d})}-\mathrm{q} \quad \mathrm{q} \neq 0 \tag{2-55}
\end{equation*}
$$

$$
\begin{aligned}
& \mathrm{G}^{*}=\mathrm{C}_{\mathrm{O}}\left[\left(\frac{\mathrm{Q}^{\prime *}}{\mathrm{Q}_{\mathrm{W}} \sqrt{\frac{\mathrm{P}}{\mathrm{P}-\mathrm{d}}}}\right)^{2}-1\right] \quad \mathrm{q} \neq 0 \\
& \text { or } \mathrm{G}^{*}=\mathrm{C}_{\mathrm{O}}\left[\frac{\mathrm{P}-\mathrm{d}}{\mathrm{P}}\left(\frac{\mathrm{Q}^{\prime *}}{\mathrm{Q}_{\mathrm{W}}}\right)^{2}-1\right]
\end{aligned}
$$

Note that in this case
-we must have $Q^{\prime *}>Q_{W} \sqrt{\frac{P}{P-d}}$, if we want $G^{*}>0$.

- when $\mathrm{d}=0$ and $q \neq 0 \Longrightarrow Q^{\prime *}=Q_{W}-q$.

## 2-11-1 Summary : EOQ Model with sale

$Q^{\prime *}=\frac{d D+I P Q_{W}}{I(P-d)}-q$,
$G^{*}= \begin{cases}\frac{C_{O}(P-d)}{P}\left(\frac{Q^{\prime *}}{Q_{W}}-1\right)^{2} & q=0 \\ C_{O}\left[\left(\frac{Q^{\prime *}}{Q_{W} \sqrt{\frac{P}{P-d}}}\right)^{2}\right] & q \neq 0\end{cases}$

## Example 2-15

The annual demand for a product of unit price $\$ 10$ is 8000 ; the annual carrying cost of $\$ 1$ is $\$ 0.30$ and the cost order is $\$ 30$. The supplier is offering a special discount during regular replenishment. He has temporarily reduced the unit price from $\$ 10$ to $\$ 9$. There are 330 working days in a year.
a)The amount of the special discount that should be purchased.
b)The time interval between 2 consecutive order
c)The time in which the special order is consumed
d)The optimal saving due to ordering the special order

## Solution

Annual $\mathrm{D}=8000, \mathrm{P}=\$ 10, \mathrm{~d}=1, \quad$ annual $\mathrm{I}=0.3, \mathrm{C}_{\mathrm{O}}=\$ 30$
a)
$Q^{\prime *}=\frac{d D}{I(P-d)}+\frac{P Q}{P-d} \quad Q=Q_{W}=\sqrt{\frac{2 D C_{O}}{I P}}=400 \quad Q^{\prime *}=3407$
b)
$T^{*}=\frac{Q^{*}}{D}=\frac{400}{8000}=\frac{1}{20} \mathrm{yr}=\frac{1}{20}(200)=10$ days
c)
$T^{\prime *}=\frac{Q^{*}}{D}=\frac{3407}{8000}=0.43 y r=0.43 \times 200 \cong 86$ days
d)
$G^{*}=\frac{C_{O}(P-d)}{P}\left(\frac{Q^{\prime *}}{Q_{W}}-1\right)^{2}=30\left(1-\frac{1}{10}\right) *\left(\frac{3407}{400}-1\right)^{2}=\$ 1525.8$
or $\mathrm{G}^{*}$ could be calculated by substituting $\mathrm{Q}^{\prime *}=3407 \mathrm{in}$ the relationship which gives G:

$$
\begin{aligned}
G^{*} & =d\left(Q^{\prime}-Q_{W}\right)+\frac{I}{2 D}\left[-d Q_{W}{ }^{2}+P Q_{W} Q^{\prime *}-(P-d) Q^{\prime * 2}\right]+\frac{C_{O} Q^{\prime *}}{Q_{W}}-C_{O} \\
& =1(3407-400)+\frac{-1 \times \frac{3}{10} \times 400^{2}+\frac{3}{10} \times 10 \times 400 \times 3407-\frac{3}{10} \times(10-1) \times 3407^{2}}{2 \times 8000}+\frac{30 \times 3407}{400}-30 \\
G^{*} & =\$ 1526.22
\end{aligned}
$$

Chapter 2 Deterministic Models
The difference in the 2 values obtained for $G^{*}$ could be due to the approximation used for fraction numbers.

It is worth knowing that $\operatorname{Martin}(1994)$ gives a more accurate formula fo the average inventory in this model; however if the discount per unit product is small the above formulae from Tersine (1194) gives acceptable answers. Based on Martin's modifications $\mathrm{Q}^{\prime *}$ and $\mathrm{G}^{*}$ would be 43401 and 1533.75 respevtively.

## 2-12E0Q Model -permanent reduction price

If we know a permanent decrease in the price will occur, no special order will be placed.

## 2-13 EOQ Model -known increase price

Suppose a supplier inform us that in the early future, the unit price increases from P to $\mathrm{P}^{\prime}=\mathrm{P}+\mathrm{a}$. Now We would like to know how much should we order with current price P before the new prices is applied(Tersine, 1994, page,117).

## Symbols

$Q^{\prime} \quad$ The special order quantity before the higher price
$q \quad$ The stock position at time when $\mathrm{Q}^{\prime}$ is placed
$Q_{a}^{*} \quad$ The economic order quantity with unit price $\mathrm{P}+\mathrm{a}$
$Q^{\prime *} \quad$ The optimal value of $\mathrm{Q}^{\prime}$
$a \quad$ The increase in unit price

## 97

Fig. 2-18 Known increase price model $\left(T_{L} \cong 0\right)$

Suppose at time $\mathrm{t}_{1}$ when the stock position is q units, an order $\mathrm{Q}^{\prime}$ of unit price P is placed. At first, suppose $T_{L} \cong 0$ i.e. the lead time is ignorable and $Q^{\prime}$ arrives at time $t_{1}$ (Fig. 2-18. The special order of $Q^{\prime}$ and the q units are enough for time $\frac{q+Q^{\prime}}{D}$, after the time $\mathrm{t}_{2}=\mathrm{t}_{1}+\frac{q+Q^{\prime}}{D}$ the new price becomes effective and the optimal order quantity will become:

$$
\begin{equation*}
Q_{a}^{*}=\sqrt{\frac{2 D C_{O}}{I(P+a)}} \tag{2-57}
\end{equation*}
$$

The total cost in period $\mathrm{t}_{2}-\mathrm{t}_{1}$ if $\mathrm{Q}^{\prime}$ is placed equals:

$$
K^{\prime}=C_{O}+C_{h}\left(\frac{q+Q^{\prime}}{2}\right)\left(t_{2}-t_{1}\right)+P\left(Q^{\prime}+q\right) \quad C_{h}=I P
$$

If no special order is placed and all orders are purchased at unit price $\mathrm{P}+\mathrm{a}$, the total cost during $\mathrm{t}_{2}-\mathrm{t}_{1}$ is as follows

$$
K=C_{0} \frac{Q^{\prime}}{Q_{a}^{*}}+I P \frac{q}{2} \frac{q}{D}+I(P+a) \frac{Q_{a}^{*}}{2} \frac{Q^{\prime}}{D}+(P+a) Q^{\prime}+P q .
$$

To determine the optimal $\mathrm{Q}^{\prime}, G=K-K^{\prime}$ i.e. the saving in total cost must be maximized:

$$
\begin{align*}
& \text { If } T_{L} \cong 0, \frac{d G}{d Q^{\prime}}=0 \Rightarrow \\
& Q^{\prime *}=Q_{a}^{*}+\frac{a\left(I Q_{a}^{*}+D\right)}{I P}-q  \tag{2-58}\\
& Q^{\prime *}=Q_{a}^{*}+\frac{a}{P}\left(Q_{a}^{*}+\frac{D}{I}\right)-q \\
& Q^{\prime *}=Q_{a}^{*}\left(1+\frac{a}{P}\right)+\frac{a D}{I P}-q \\
& Q^{\prime *}=(P+a) \frac{Q_{a}^{*}}{P}+\frac{a D}{I P}-q
\end{align*}
$$

The optimum cost saving is(Tersine, 1994, page 119):

$$
\begin{equation*}
G^{*}=C_{O}\left[\left(\frac{Q^{\prime^{*}}}{Q_{W}}\right)^{2}-1\right] \tag{2-59}
\end{equation*}
$$

If the lead time is considerable then q is reduced to $q-D T_{L} \mathrm{Q}^{\prime}$ arrive and we have

$$
\begin{equation*}
Q^{\prime *}=(P+a) \frac{Q_{a}^{*}}{P}+\frac{a}{I P} D-\left(q-D T_{L}\right) \tag{2-60}
\end{equation*}
$$

If the $Q^{\prime}$ could be placed when the stock position reaches reorder point i.e. $q=R O P$, then (Tersine, 1994,page 120)

$$
\begin{equation*}
Q^{\prime *}=(P+a) \frac{Q_{a}^{*}}{P}+\quad \text { If } q=R O P \tag{2-61}
\end{equation*}
$$

$\frac{a D}{I P}$

$$
\begin{equation*}
G^{*}=C_{O}\left(\frac{Q^{\prime *}}{Q_{W}}-1\right)^{2} \quad \text { If } q=R O P \tag{2-62}
\end{equation*}
$$

## Example 2-16

The annual demand for a product is 8000 , the supplier is going to increase the current price $\$ 10$ to $\$ 11$ from the beginning of the next year. The cost of each order is $\$ 30$, the lead time is 2 weeks, and the carrying cost of $\$ 1$ per year is $\$ .03$. What amount should be purchased on the last day of this year before the price increase if the stock position is $q=346$. What is the saving with this action? There are 52 working in a year?

## Solution

$$
\begin{aligned}
& \mathrm{a}=1 ، \mathrm{P}=10 \quad Q_{W}=\sqrt{\frac{2 D C_{O}}{I P}}=400 \quad Q_{a}^{*}=\sqrt{\frac{2 D C_{O}}{I(P+a)}}=381 \\
& \begin{aligned}
& Q^{\prime *}=Q_{a}^{*}+\frac{a}{I P}\left(I Q_{a}^{*}+D\right)-q+D T_{L} \\
&=381+\frac{1}{0.3 \times 10}(0.3 \times 381+8000)-346+8000 \times \frac{2}{52}=3048
\end{aligned} \\
& R O P=D T_{L}=8000 \times \frac{2}{50}=307
\end{aligned}
$$

Since $\neq R O P, G^{*}$ has to be calculated using Eq. 2-62:

$$
\mathrm{G}^{*}=\mathrm{C}_{\mathrm{O}}\left[\left(\frac{\mathrm{Q}^{* *}}{\mathrm{Qw}^{2}}\right)^{2}-1\right]=30 \times\left[\left(\frac{3048}{400}\right)^{2}-1\right]=1712
$$

The above calculations show that at the end of the year an order of 3048 units with price $\$ 10$ has to placed; this amount is consumed in $\frac{3048}{8000}=0.381$ year; bringing $\$ 1712$ saving. The next orders would be of amount 381 units and unit price $\$ 11$.

## Economic Production Quantity(EPQ) Models

This model, which is also called finite production rate model or manufacturing model has the following types:

Chapter 2 Deterministic Models
$\left\{\begin{array}{l}a-\text { single item model }\left\{\begin{array}{l}1-\text { stockout not permitted } \\ 2-\text { stockout permitted }\end{array}\right. \\ b-\text { Multiple item model }\left\{\begin{array}{l}1-n \text { items on } n \text { machines } \\ 2-\text { machine for all items }\left\{\begin{array}{l}1-C_{o} \cong 0 \\ 2-C_{0} \neq 0\end{array}\right.\end{array}\right.\end{array}\right.$

The models are described below.

## 2-14 Economic Production Quantity-single item

To deal with EPQ model, when we have single item, two cases are distinguished: either stockout is permitted or it is not permitted.

## 2-14-1 EPQ -single item,stockout unpermitted

In this model, it is assumed that a product is consumed with annual rate D at the same time it is produced gradually with annual rate $\mathrm{R}>\mathrm{D}$ and therefore the remaining is stored with annual rate R-D in the ware- house simultaneously. No stockout is permitted. Needlesas to say that this model exists if $\mathrm{R}>\mathrm{D}$.

Fig.2-19 EPQ model or Gradual arrival model

The annual total cost is:

$$
T C=C_{O} \frac{D}{Q}+C_{h} \bar{I}+P D
$$

Where Q is the order quantity and $\bar{I}$ is the average inventory.
Referring to Fig 2-19:

$$
\begin{aligned}
& \boldsymbol{T}=\frac{\mathbf{Q}}{\mathbf{D}}, \boldsymbol{t}_{\boldsymbol{P}}=\frac{\boldsymbol{I}_{\mathrm{Max}}}{\boldsymbol{R - D}} \\
& \bar{I}=\frac{\mathrm{I}_{\mathrm{max}} \times T}{2 T}=\frac{\mathrm{I}_{\max }}{2} \quad I_{\operatorname{Max}}=\frac{Q}{R}(R-D)=Q\left(1-\frac{D}{R}\right) \Rightarrow \\
& \bar{I}=\frac{Q\left(1-\frac{D}{R}\right)}{2} \\
& T C==\frac{C_{o D} D}{Q}+C_{h} \frac{Q\left(1-\frac{D}{R}\right)}{2}+P D
\end{aligned}
$$

If Q is continuous, since $\frac{d^{2} T C}{d Q^{2}}>0$, then the function TC has minimum which satisfies $\frac{d T C}{d Q}=0$. This equation yields:

$$
Q^{*}=E P Q=\sqrt{\frac{2 D C_{O}}{I P\left(1-\frac{D}{R}\right)}} \quad R>D \quad(2-63)
$$

Let the sum of carrying cost and order cost for one year be dented by $\boldsymbol{T V C}=\boldsymbol{C}_{\boldsymbol{O}} \frac{\boldsymbol{D}}{\boldsymbol{Q}}+\boldsymbol{C}_{\boldsymbol{h}} \bar{I}$; substituting $\boldsymbol{Q}^{*}$ from Eq.2-63 in TVC yields:

$$
T V C^{*}=\sqrt{2 D C_{0} C_{h}\left(1-\frac{D}{R}\right)} \quad(2-64-1)
$$

$$
\begin{array}{ll}
T V C^{*}=C_{h} Q^{*}\left(1-\frac{D}{R}\right) & (2-64-2) \\
T V C^{*}=C_{h} Q_{w} \sqrt{1-\frac{D}{R}} & (2-64-3)
\end{array}
$$

In this model if $\mathbf{D}=\mathbf{R}$ or $\frac{D}{R}=\mathbf{1}$, no inventory is deposited. If the production rate or the purchase rate is $\operatorname{largish} \frac{\boldsymbol{D}}{\boldsymbol{R}} \cong \mathbf{0}$ and the model converts to the classic EOQ model.

## 2-14-1-1 The reorder point in EPQ model -single item

If the time of consumption in each cycle time is $t_{D}$ ( line HS in Fig.2-19) then the reorder point would be (Hajji, 2012 page 66):

$$
\begin{align*}
& R O P=r_{h}= \\
& \begin{cases}D T_{L}-K Q \\
T_{L}(D-R)+(K+1)\left(\frac{R}{D}-1\right) Q & T_{L}-K T<t_{D} \\
T_{L}-K T>t_{D}\end{cases} \tag{2-65}
\end{align*}
$$

Where $K=\left[\frac{T_{L}}{T}\right]$ and $T_{L}$ is the lead time.

## Example 2-16

50 tons of a kind of chemical fertilizer is produced in a workshop . The fertilizer contains $30 \%$ urea which is produced in another workshop which could produce 20 tons urea per year. $\mathrm{T}_{\mathrm{L}}=2$ days and for each setup the workshop shuts down for 2 working days but 10 people have to adjust and fix the machine for producing urea. When The workshop incurs A dollars during the shutdown and pays $\$ 10$ per hour to each of these 10 people. There are 8 hours in each working day. The cost of producing 1 ton urea is P and annual $\mathrm{I}=0.1$. Find the
optimum values for Q , production time $\left(\mathrm{t}_{\mathrm{p}}\right)$ and cycle time $(\mathrm{T})$. Stockout is not permitted.

## Solution

For the production of urea:
$\mathrm{R}=20 ; \mathrm{D}=50 \times .30=15 . y r \quad \mathrm{C}_{\mathrm{O}}=(2 \times 8 \times 10 \times 10)+2 * \mathrm{~A}=1600+2 \mathrm{~A}$
If $A$ is given the following relationship could be used :
$Q^{*}=\sqrt{\frac{2 \times 15 \times C_{O}}{(0.1) P\left(1-\frac{D}{20}\right)}}$
$t_{P}^{*}=\frac{Q^{*}}{R}$
$T^{*}=\frac{Q^{*}}{D}$.

End of example
The following table compares some relationships in EOQ and EPQ models.

| Chapter 2 Deterministic M |  | 104 |
| :---: | :---: | :---: |
|  | EPQ | EOQ |
| Order Quantity | $\mathrm{Q}^{*}=\frac{\mathrm{Q}_{\mathrm{W}}}{\sqrt{1-\frac{\mathrm{D}}{\mathrm{R}}}}$ | $\mathrm{Q}_{\mathrm{W}}$ |
| Maximum inventory on hand | $\mathrm{Q}_{\mathrm{W}} \sqrt{1-\frac{\mathrm{D}}{\mathrm{R}}}=\mathrm{Q}^{*}\left(1-\frac{\mathrm{D}}{\mathrm{R}}\right)$ | $\mathrm{Q}_{\mathrm{W}}$ |
| Average inventory | $\frac{\mathrm{QW}}{2} \sqrt{1-\frac{\mathrm{D}}{\mathrm{R}}=\frac{\mathrm{Q}^{*}}{2}\left(1-\frac{\mathrm{D}}{\mathrm{R}}\right)}$ | $\frac{\mathrm{Q}_{\mathrm{W}}}{2}$ |
| TVC | $\sqrt{2 D C_{0} C_{h}\left(1-\frac{D}{R}\right)}$ | $\sqrt{2 \mathrm{DC}_{0} \mathrm{C}_{\mathrm{h}}}$ |
| TVC | $\mathrm{Q}_{\mathrm{W}} \mathrm{C}_{\mathrm{h}} \sqrt{1-\frac{\mathrm{D}}{\mathrm{R}}}$ | $\mathrm{Q}_{\mathrm{W}} \mathrm{C}_{\mathrm{h}}$ |
| TC | $\sqrt{2 D C_{0} C_{h}\left(1-\frac{D}{R}\right)}+$ PD | $\sqrt{2 \mathrm{DC} \mathrm{O}_{0} \mathrm{C}_{\mathrm{h}}}$ $+\mathrm{P}^{\prime}$ |

There are some variations for EPQ model including discounted EPQ model, EPQ model with stockout. The description of backordered EPQ model follows.

## 2-14-2 Single-item EPQ model with backorders

In a Single-item backordered EPQ model, as depicted in Fig. 2-20, when the inventory reaches zero the production phase does not start and the demand continues with rate D . When the shortage reaches the allowable amount $b$ the production phase begins.

## Symbols

b maximum allowable shortage
$\pi$ fixed shortage cost per unit
$\hat{\pi} \quad$ shortage cost per unit product per year $(\hat{\pi} \neq 0)$
It is assumed that $\hat{\pi} \neq 0$ and when the production starts again and the product arrives, the backorders are fulfilled.

To Find the optimal order quantity $(\mathrm{Q})$ and maximum allowable shortage(b), the total cost of the model has to be written and its partial derivatives be set to zero. The final results are:

$$
\begin{array}{ll}
Q^{*}=\sqrt{\frac{2 D C_{O}}{C_{h}\left(1-\frac{D}{R}\right)}-\frac{\pi^{2} D^{2}}{C_{h}\left(C_{h}+\hat{\pi}\right)}} \sqrt{\frac{\hat{\pi}+C_{h}}{\hat{\pi}}} & (2-6 \\
b^{*}=\frac{\left[C_{h} Q^{*}-\pi D\right]\left(1-\frac{D}{R}\right)}{\hat{\pi}+C_{h}} & (2-67 \\
I_{\max }^{*}=Q^{*}\left(1-\frac{D}{R}\right)-b^{*} & \tag{2-68}
\end{array}
$$

Fig. 2-20 A single-item EPQ inventory model with backorder
2-14-2-1 EPQ model with backorder - $\pi=0$ \& $\widehat{\pi} \neq 0$
Substituting $\boldsymbol{\pi}=\mathbf{0}$ in Eqs. 2-66 \& 2-67 results in the followings:

$$
\begin{gathered}
\mathrm{Q}^{*}=\sqrt{\frac{2 \mathrm{DC} C_{0}}{C_{h}\left(1-\frac{D}{D}\right)}} \sqrt{\frac{\hat{\pi}+C_{h}}{\hat{\pi}}} \\
\mathrm{TVC}^{*}=\sqrt{2 \mathrm{DC}_{0} C_{h}\left(1-\frac{D}{R}\right)} \sqrt{\frac{\hat{\pi}}{\hat{\pi}+C_{h}}} \\
\mathrm{TVC}^{*}=\mathrm{C}_{\mathrm{h}} \mathrm{Q}_{\mathrm{W}} \sqrt{\left(1-\frac{D}{R}\right) \frac{\hat{\pi}}{\widehat{\pi}+C_{h}}} \\
\mathrm{TVC}^{*}=\mathrm{C}_{\mathrm{h}} \mathrm{Q}^{*}\left(1-\frac{\mathrm{D}}{\mathrm{R}}\right) \sqrt{\frac{\hat{\pi}}{\hat{\pi}+C_{h}}}
\end{gathered}
$$

It is worth mentioning that optimal $b$ reduces to $\boldsymbol{b}^{*}=\frac{1-\frac{D}{R}}{1+\frac{\pi}{c_{h}}} \boldsymbol{Q}^{*}$ when $\boldsymbol{\pi}=\mathbf{0}$.

## 2-15 Make or Buy Decision

A make-or-buy decision involves an act of using cost-benefit to make a choice between manufacturing a product internally or purchasing it from an external source. To cope with this decision problem , use EOQ model for buying and EPQ model for manufacturing , choose the one with less total cost (TC not TVC).

## 2-16 Economic Production Quantity:Multiple-item

## Symbols

$\left(\mathrm{C}_{\mathrm{h}}\right)_{\mathrm{i}} \quad$ Annual holding cost for product \# i
$\left(\mathrm{C}_{0}\right)_{\mathrm{i}} \quad$ Setup cost for product \# i
$\mathrm{D}_{\mathrm{i}} \quad$ Annual demand for product \# i
$\mathrm{d}_{\mathrm{i}}=\frac{D_{i}}{N} \quad$ daily demand for product \# i
$\overline{\bar{I}_{\mathrm{i}}} \quad$ Average inventory of product \# i
$m=\frac{D_{i}}{Q_{i}} \quad$ Annual number of cycles (production runs)
$\mathrm{N} \quad$ Number of working days in a year
$\mathrm{P}_{\mathrm{i}} \quad$ Unit production cost of product \# i
$Q_{i} \quad$ Order Quantity for product \# I per cycle
$\mathrm{R}_{\mathrm{i}} \quad$ Annual potential production rate of product \# i
$\mathrm{S}_{\mathrm{i}} \quad$ The setup time required for product \# i
$\left(\mathrm{t}_{\mathrm{p}}\right)_{\mathrm{i}} \quad$ The production time for product \# i
$t_{P_{i}} \quad$ Optimal $\left(\mathrm{t}_{\mathrm{p}}\right)_{\mathrm{i}}$
$T^{*} \quad$ The time between two successive setups
$T C_{i} \quad$ annual total cost of product \# i
$T_{o}^{*} \quad$ The time between two successive setups for the case the setup times are negligible

For determining the production quantity of each product in multiple- item EPQ, 2 cases are distinguished: case 1 in which each of our $n$ products are produced on $n$ separate machines and case 2 in which our $n$ products are produced on only one machine or station where the number of cycles are the same for all n products.

## 2-16-1 Multiple-item EPQ model: $n$ machines for $n$ products with no constraints

When we have n products that could be manufactured on n separate machines and there is no constraint, the purpose of is to determine the optimal production lot size of each product in order to minimize the total cost (TC)of system including set up costs, holding costs of raw materials and finished products as well as production costs i.e.

$$
T C=\sum_{i=1}^{n} T C_{i}=\sum_{i=1}^{n} \frac{C_{O_{i} D_{i}}}{Q_{i}}+\sum_{i=1}^{n} \frac{C_{h_{i}}}{2} Q_{i}\left(1-\frac{D_{i}}{R_{i}}\right)+\sum_{i=1}^{n} P_{i} D_{i} .
$$

To find the optimal values of $Q_{i}$ 's, the partial derivatives are set equal to zero:

$$
\begin{aligned}
& \frac{\partial T C}{\partial Q_{i}}=0 \Rightarrow-\frac{C_{O_{i}} D_{i}}{Q_{i}^{2}}+\frac{C_{h_{i}}}{2}\left(1-\frac{D_{i}}{R_{i}}\right)=0 \quad \Rightarrow \\
& Q_{i}^{*}=\sqrt{\frac{2 D_{i} C_{O_{i}}}{C_{h_{i}}\left(1-\frac{D_{i}}{R_{i}}\right)}} \quad i=1,2, \ldots, n \quad(2-70)
\end{aligned}
$$

The optimal total cost and cycle times are obtained from:

$$
\begin{align*}
& T C^{*}=\sum_{i=1}^{n} \sqrt{2 D_{i} C_{O_{i}} C_{h_{i}}\left(1-\frac{D_{i}}{R_{i}}\right)}+\sum_{i=1}^{n} P_{i} D_{i} \quad(2-71) \\
& T_{i}^{*}=\frac{Q_{i}^{*}}{D_{i}} \tag{2-72}
\end{align*}
$$

The required time for producing product \# i is derived from $t_{p_{i}}=\frac{Q_{i}}{R_{i}}$.
If we use Fig 2-19,the average inventory of Product No. i is calculated as follows:

Chapter 2 Deterministic Models
$\bar{I}_{i}=\frac{\frac{(O S)(H M)}{2}}{O S}=\frac{H M}{2}=\frac{\left(R_{i}-D_{i}\right) t_{p_{i}}}{D_{i}^{2}} \Rightarrow$
$\bar{I}_{i}=\frac{R_{i}-D_{i}^{\text {O }} Q_{i}}{2}\left(\frac{Q_{i}}{R_{i}}\right)=\frac{Q_{i}}{2}\left(1-\frac{D_{i}}{R_{i}}\right)$,
and the maximum inventory of product \# i would be equal to:

$$
\left.I_{\text {Max }}\right)_{i}=\left(R_{i}-D_{i}\right) t_{P_{i}}
$$

In this model the annual number of setups for a product in not necessarily equal to that of the other product.

## 2-16-1 Multiple-item EPQ model: 1 machine for $n$ products

Suppose would like to apply EPQ model to plan manufacturing of n products on the same machine and each product has to be produced m times a year. The following assumptions are needed in the multipleitem EPQ model
-Each tome, only one product is produced on the machine

- The number of setups and cycles for manufacturing all $n$ products are assumed the same and constant.
-The number denoted by $m$ equals $m=\frac{D_{i}}{Q_{i}}, i=12, \ldots, n$.
- The reciprocal of $m$ is the time between two consecutive: $T=\frac{1}{\mathrm{~m}}$.
$-D_{i}, R_{i}$, demand and production rates for product $\# \mathrm{i}$, ares assumed the same during all production cycle times and so is the production rate.
-The setup cost for product \# i is assumed independent of the order of producing the items on the machine

To deal with this model, 2 situations are supposed to be discussed:
Either the setup times are negligible ( $S_{i} \cong 0$ ) or they are considerable and cannot be ignored $\left(S_{i} \neq 0\right)$.

## 2-16-2-1 Multiple-item EPQ model: 1 machine $\boldsymbol{\&}_{S_{i}} \cong 0$

Here we would like to consider the multiple-item EPQ model having 1 machine with negligible setup times ( $S_{i} \cong 0$ ) available for producing n products (Fig. 2-21) where $\frac{D_{i}}{R_{i}}<1 \quad i=1,2, \ldots, n$.

Fig. 2-21 EPQ model-multiple item\& $S_{i}=0$
To reach reasonable results in this model, as you will notice later, we must have $\sum_{i=1}^{n} \frac{D_{i}}{R_{i}}<1$. The average inventory of product $\# \mathrm{i}$ could be written as follows:

$$
\overline{I_{i}}=\left(\frac{R_{i}-D_{i}}{2}\right)\left(\frac{Q_{i}}{R_{i}}\right)=\frac{Q_{i}}{2}\left(1-\frac{D_{i}}{R_{i}}\right)=\frac{D_{i}}{2 \mathrm{~m}}\left(1-\frac{D_{i}}{R_{i}}\right),
$$

Therefore the total cost of Product \# i is:

$$
T C_{i}=C_{O_{i}} m+C_{h_{i}} \times \frac{D_{i}}{2 m}\left(1-\frac{D_{i}}{R_{i}}\right)+P_{i} D_{i}=C_{O_{i}} \frac{D_{i}}{Q_{i}}+\frac{C_{h_{i}}}{2} Q_{i}\left(1-\frac{D_{i}}{R_{i}}\right)+P_{i} D_{i},
$$

The total cost of the system:

$$
\begin{aligned}
& T C=\sum_{i=1}^{n} T C_{i}=\sum_{i=1}^{n} C_{O_{i}} m+\sum_{i=1}^{n} C_{h_{i}}\left(\frac{D_{i}}{2 m}\left(1-\frac{D_{i}}{R_{i}}\right)\right)+\sum_{i=1}^{n} P_{i} D_{i} . \\
& \frac{d T C}{d m}=0 \Rightarrow
\end{aligned}
$$

$$
\begin{equation*}
m^{*}=\sqrt{\frac{\sum_{i=1}^{n}\left(C_{h}\right)_{i} D_{i}\left(1-\frac{D_{i}}{R_{i}}\right)}{2 \sum_{i=1}^{n}\left(C_{O}\right)_{i}}} \tag{2}
\end{equation*}
$$

then

$$
\begin{gather*}
T C^{*}=T C\left(m^{*}\right)=2 m^{*} \sum_{i=1}^{n}\left(C_{0}\right)_{i}+\sum_{i=1}^{n} P_{i} D_{i} \quad(2-74) \\
Q_{i}^{*}=\frac{D_{i}}{m^{*}}=D_{i} T_{0}^{*} \tag{2-75}
\end{gather*}
$$

Let $T_{0}$ dentote the cycle time when the setup times are negligible; then:

$$
\begin{equation*}
T C^{*}=\frac{2 \sum_{i=1}^{n}\left(C_{o}\right)_{i}}{T_{0}^{*}}+\sum_{i=1}^{n} P_{i} D_{i} \tag{2-76}
\end{equation*}
$$

where $T_{0}^{*}=\frac{1}{m^{*}}$.
This EPQ model cannot be use unless $\sum_{i=1}^{n} \frac{D_{i}}{\frac{R_{i}}{N}}$ (Tersine, 1994, page 128).; or $\sum_{i=1}^{n} \frac{D_{i}}{R_{i}}<1$. The difference of right hand side from left hand side is dented by $\alpha$ which is a dimentionless ratio:

$$
\begin{equation*}
\alpha=1-\sum_{i=1}^{n} \frac{\mathrm{D}_{\mathrm{i}}}{\mathrm{R}_{\mathrm{i}}} \tag{2-77}
\end{equation*}
$$

$\alpha$ is sometimes called the free or idle time of the station or the machine used for production. That is because $\alpha N$ is the number of working days the machine is idle.This time in year is equal to $\frac{\alpha N}{N}=\alpha$. The multiple- item EPQ model has feasible answer if $\alpha>0$. In this model

$$
\begin{equation*}
T_{0}^{*}=\sqrt{\frac{2 \sum_{\mathrm{i}=1}^{\mathrm{n}}\left(\mathrm{C}_{\mathrm{o}}\right)_{\mathrm{i}}}{\sum_{\mathrm{i}=1}^{\mathrm{n}}\left[\left(\mathrm{C}_{\mathrm{h}}\right)_{\mathrm{i}} \mathrm{D}_{\mathrm{i}}\left(1-\frac{D_{i}}{R_{i}}\right)\right.}} \tag{2-78}
\end{equation*}
$$

Note that $T_{0}^{*}$ is also valid for the case in which the setup times $\left(S_{i}\right)$ are not zero but their sum in a year is less than $\alpha$;however, if their
sum is greater than $\alpha$, as you will see later if $\alpha=1-\sum_{i=1}^{n} \frac{D_{i}}{R_{i}}>0$ the cycle time is calculated from $T^{*}=\operatorname{Max}\left\{T_{0}^{*}, \frac{\sum_{i=1}^{n} s_{i}}{\alpha}\right\}$.

## Example 2-18

What do you suggest the production cycle for the group of products in the following table. Assume $S_{1}=S_{2}=S_{3}=S_{4}=S_{5} \cong 0$ and 250 working days per year . what is the optimal production run size and total cost(Tersine, 199, page 129).

| $\begin{aligned} & \square \\ & 0 \\ & \stackrel{\rightharpoonup}{0} \\ & \end{aligned}$ | Annual Demand | $$ | Daily <br> produ <br> ction <br> rate | Annua l holdin $\stackrel{\mathrm{g}}{\mathrm{Cost}}$ per unit | Setup cost |
| :---: | :---: | :---: | :---: | :---: | :---: |
| i | $\mathrm{D}_{\mathrm{i}}$ | $\mathrm{P}_{\mathrm{i}}$ |  | $\mathrm{C}_{\text {hi }}$ | $\left(\mathrm{C}_{0}\right)_{\mathrm{i}}$ |
| 1 | 5000 | 6 | 100 | 1.6 | 30 |
| 2 | 1000 | 5 | 400 | 1.4 | 25 |
| 3 | 7000 | 3 | 350 | 0.6 | 30 |
| 4 | 15000 | 4 | 200 | 1.15 | 27 |
| 5 | 4000 | 6 | 100 | 1.65 | 80 |
| sum |  |  |  |  | 202 |

## Solution

$$
\begin{aligned}
& \alpha=1-\sum_{i=1}^{n} \frac{D_{i}}{R_{i}} \\
& =1-\left(\frac{5000}{250 \times 100}+\frac{10000}{250 \times 400}+\frac{7000}{250 \times 350}+\frac{15000}{250 \times 200}+\frac{4000}{250 \times 100}\right)=0.16
\end{aligned}
$$

Since $\alpha>0$, the problem has answer to the optimal production runs(m*).

$$
m^{*}=\sqrt{\frac{\sum_{i=1}^{n}\left(C_{h}\right)_{i} D_{i}\left(1-\frac{D_{i}}{R_{i}}\right)}{2 \sum_{i=1}^{n}\left(C_{O}\right)_{i}}}=\sqrt{\frac{40483}{2 \times 202}} \cong 10 .
$$

This means the there are 10 runs per year for each product to meet the corresponding demands.

When the setup times are negligible ( $S_{i} \cong 0$ ), the number of production runs are dented by $m_{0}$ whose oiptimal value in the example is $m_{0}^{*}=10$. The production cycle (the time between 2 successive production runs for each of the 5 products is equal to $: T_{0}^{*}=\frac{1}{m_{0}^{*}}=\frac{1}{10} y r$.

The production run size for each product calculated from $Q_{j}^{*}=D_{j} T_{0}^{*} \quad j=1,2,3,4,5$ is given in the following table:

|  |  |  | Production run size | number of days in each cycle machine busy producing $\mathrm{Q}_{\mathrm{i}}^{*}$ |
| :---: | :---: | :---: | :---: | :---: |
| i | $\mathrm{D}_{\mathrm{i}}\left(1-\frac{D_{i}}{R_{i}}\right.$ ) | $\begin{aligned} & \mathrm{C}_{\mathrm{h}_{\mathrm{i}}} \mathrm{D}_{\mathrm{i}}(1 \\ & \left.-\frac{\mathrm{D}_{\mathrm{i}}}{\mathrm{R}_{\mathrm{i}}}\right) \end{aligned}$ | $\mathrm{Q}_{\mathrm{i}}^{*}=\frac{\mathrm{D}_{\mathrm{i}}}{\mathrm{m}^{*}}=\mathrm{D}_{\mathrm{i}} \mathrm{T}^{*}$ | $\mathrm{tp}_{\mathrm{i}}=\frac{\mathrm{Q}_{\mathrm{i}}^{*}}{\mathrm{R}_{\mathrm{i}}}$ |
| 1 | 4000 | 6400 | 500 | 5 |
| 2 | 9000 | 12600 | 1000 | 2.5 |
| 3 | 6440 | 4864 | 700 | 2 |
| 4 | 1500 | 12074 | 1500 | 7.5 |
| 5 | 3360 | 5544 | 400 | 4 |
| su |  | 40483 |  | 21 |
| Note: $R_{i}$ is the annual production rate for product \#i. e.g. $R_{1}=250 \times 100=25000$ |  |  |  |  |

The machine cycle time is $\frac{\mathrm{N}}{\mathrm{m}^{*}}=\frac{250}{10}=25$ days and according to
the above table $\sum_{i=1}^{5} \mathrm{t}_{\mathrm{P}_{\mathrm{i}}}=5+2.5+2+7.5+4=21$ days. Then in each cycle the machine is idle for 4 days. The optimal total cost is given by Eq.2-74:

$$
\begin{aligned}
& T C\left(m^{*}\right)=2 m^{*} \sum_{i=1}^{n}\left(C_{O}\right)_{i}+\sum_{i=1}^{n} D_{i} P_{i} \\
& T C\left(m^{*}\right)=2(10)(202)+(30000+50000+21000+60000+24000) \\
&=189040
\end{aligned}
$$

## End of example.

## 2-16-2-2 Multiple-item EPQ model: 1 machine $\& S_{i} \neq 0$

This section deals with multiple-item EPQ model when the machine setup time for each product is not negligible and the production runs $(\mathrm{m})$ for each product in a year is such that:

$$
m=\frac{D_{1}}{Q_{1}}=\ldots=\frac{D_{n}}{Q_{n}} ;
$$

and the cycle time is equal to :

$$
\mathrm{T}=\frac{\mathrm{Q}_{1}}{\mathrm{D}_{1}}=\cdots=\frac{\mathrm{Q}_{\mathrm{n}}}{\mathrm{D}_{\mathrm{n}}} .
$$

The time required by the machine to produce the amount $\boldsymbol{Q}_{\boldsymbol{j}}$ of product \#j is

$$
t_{P_{j}}=\frac{Q_{j}}{R_{j}} \quad j=1,2, \ldots, n .
$$

Let T denote the time between two successive setups for product j including the non zero setup time $S_{j}: T=\frac{Q_{j}}{D_{j}}$.

The optimal $\mathrm{T}\left(T^{*}=\frac{Q_{j}^{*}}{R_{j}}\right.$ is not less than $T_{0}^{*}$ (the time between two successive setups for product j when $\left.S_{j}=0\right): \mathrm{T}^{*} \geq \mathrm{T}^{*}{ }_{0}$

In each machine cycle time, each product is produced once and It is obvious that:

$$
\sum S_{j}+\sum t_{P_{j}} \leq T \quad \sum S_{j}+\sum \frac{Q_{j}}{R_{j}} \leq T
$$

The number of production runs for product j to produce amount $D_{j}$ is equal to $m=\frac{D_{j}}{Q_{j}}$ and in the optimal state $m^{*}=\frac{D_{j}}{Q_{j}^{*}}$.

Since $\sum S_{j}+\sum \frac{Q_{j}}{R_{j}} \leq T$ and $Q_{j}^{*}=D_{j} T^{*}$ then
$\sum S_{j}+\sum \frac{D_{j}}{R_{j}} T^{*} \leq T^{*} \Rightarrow T^{*} \geq \frac{\sum S_{j}}{1-\sum_{j=1}^{n} \frac{D_{j}}{R_{j}}}$
Let $T_{\text {min }}=\frac{\sum s_{j}}{1-\sum_{j=1}^{n} \frac{D_{j}}{R_{j}}}$ therefore $T^{*} \geq T_{\text {min }}$
Considering Eq. (I) \& (II) we could write:

$$
\begin{equation*}
\mathrm{T}^{*}=\operatorname{Max}\left\{\mathrm{T}_{0}^{*}, \mathrm{~T}_{\min }\right\} \tag{2-79}
\end{equation*}
$$

where

$$
T_{0}^{*}=\sqrt{\frac{2 \sum_{\mathrm{i}=1}^{\mathrm{n}}\left(\mathrm{C}_{\mathrm{o}}\right)_{\mathrm{i}}}{\sum_{\mathrm{i}=1}^{\mathrm{n}}\left(\mathrm{C}_{\mathrm{h}}\right)_{\mathrm{i}} \mathrm{D}_{\mathrm{i}}\left(1-\frac{D_{i}}{R_{i}}\right)}} \quad T_{\min }=\frac{\sum_{j=1}^{n} S_{j}}{1-\sum_{j=1}^{n} \frac{D_{j}}{R_{j}}}=\frac{\sum S_{j}}{\alpha}
$$

$\alpha=1-\sum_{j=1}^{n} \frac{D_{j}}{R_{j}}>0$ is a necessary condition for the existence $\mathrm{T}^{*}$.
Note that:

- $\mathrm{S}_{\mathrm{j}}$ 's are not necessarily equal.
-production run size is

$$
\begin{equation*}
Q_{j}^{*}=D_{j} T^{*} \tag{2-80}
\end{equation*}
$$

-Eq. (2-79) is also applicable when setup times are zero.

## Example 2-19

Assuming 250 working days in ayear solve example 2-18 again if

$$
\left(\mathrm{aS}_{1}=\mathrm{S}_{2}=\mathrm{S}_{3}=\mathrm{S}_{4}=\mathrm{S}_{5}=0.5=\right.\text { half a day }
$$

b) $S_{j}=1$ day $\quad j=1, . ., 5$

## Solution

a)

The necessary condition $\alpha=1-\sum_{j=1}^{5} \frac{D_{j}}{R_{j}}=0.16>0$ holds therefore Eq. 2-79 could be utilized:

$$
\begin{aligned}
& \alpha=1-\sum_{j=1}^{5} \frac{D_{j}}{R_{j}}=1-\frac{20}{100}-\frac{40}{400}-\frac{28}{350}-\frac{60}{200}-\frac{16}{100}=\frac{40}{250}=0.16 \\
& m^{*}=\frac{1}{T^{*}} \\
& T^{*}=M^{*}\left\{T_{0}^{*}, T_{\min }\right\} \\
& T_{\min }=\frac{\sum_{j=1}^{5} S_{j}=2.5 \text { days }=\frac{1}{100} \mathrm{yr}}{1-\sum_{j=1}^{5} \frac{D_{j}}{R_{j}}}=\frac{\frac{5(0.5)}{1-\frac{20}{100}-\frac{40}{400}-\frac{28}{350}-\frac{60}{200}-\frac{16}{100}}}{}=\frac{2.5}{0.16} d a y=\frac{2.5}{0.16} \times \frac{1}{250}=\frac{1}{16} \mathrm{yr} \\
& T_{0}^{*}=\sqrt{\frac{2 \sum_{i=1}^{n}\left(C_{O}\right)_{i}}{\sum_{i=1}^{n}\left(C_{h}\right)_{i} D_{i}\left(1-\frac{D_{i}}{R_{i}}\right)}}=\sqrt{\frac{2 \times 202}{40483}}=\frac{1}{10} \mathrm{yr} \Rightarrow \\
& T^{*}=\operatorname{Max}\left\{\frac{1}{10}, \frac{1}{16}\right\}=\frac{1}{10} \mathrm{yr} \quad \mathrm{~m}^{*}=\frac{1}{T^{*}}=10
\end{aligned}
$$

The production quantities in each run are obtained from

$$
Q_{j}=D_{j} T^{*}=\frac{D_{j}}{10} \quad j=1,2,3,4,5
$$

Therefore

$$
\mathrm{Q}_{1}=\frac{\mathrm{D}_{1}}{10}=500 \quad \mathrm{Q}_{2}=1000 \quad \mathrm{Q}_{3}=700 \quad \mathrm{Q}_{4}=1500 \quad \mathrm{Q}_{5}=400
$$

b) $T^{*}=\operatorname{Max}\left\{T_{0}^{*}, T_{\min }\right\} \quad T_{0}^{*}=\frac{1}{10} \mathrm{yr}, S_{j}=1$ day , then:
$T_{\text {min }}=\frac{\sum s_{j}}{1-\sum_{j=1}^{5} \frac{D_{j}}{R_{j}}}=\frac{(5)(1)}{1-\frac{20}{100}-\frac{40}{400}-\frac{28}{350}-\frac{60}{200}-\frac{16}{100}}=\frac{5}{0.16} \quad$ day
$\mathrm{T}_{\min }=\frac{5}{0.16} \times \frac{1}{250}=\frac{1}{8} \mathrm{yr}, \mathrm{T}_{0}^{*}=\frac{1}{10} \mathrm{yr}$
$T^{*}=\operatorname{Max}\left\{\frac{1}{10}, \frac{1}{8}\right\}=\frac{1}{8} \mathrm{yr}, \quad \mathrm{m}^{*}=\frac{1}{T^{*}}=8 \quad Q_{j}=D_{j} / m^{*}$
$\mathrm{Q}_{1}=\mathrm{D}_{1} \mathrm{~T}^{*}=5000 \times \frac{1}{8}=625, \mathrm{Q}_{2}=1250, \mathrm{Q}_{3}=875, \mathrm{Q}_{4}=1875$,
$Q_{5}=500$

## 2-17 Multiple-item EOQ model

In this section, EOQ model is extended to simultaneous purchase of several items. Here we either have a constraint such as the having a case where the number of orders for all items must be the same or we may not have any constraint or precondition.

## 2-17-1 Unconstrianed multiple-item EOQ model

In a multiple -item EOQ model in which there is no constrain or preconditions, and the items could be dealt separately e.g. our $n$ products could be bought from n suppliers, the optimal order quantity for each item is derived as follows:

$$
\begin{aligned}
& T C_{i}=C_{O_{i}} \frac{D_{i}}{Q_{i}}+C_{h_{i}} \frac{Q_{i}}{2}+P_{i} D_{i} \\
& T C=\sum_{i=1}^{n} T C_{i}=\sum_{i=1}^{n}\left(C_{O_{i}} \frac{D_{i}}{Q_{i}}+C_{h_{i}} \frac{Q_{i}}{2}+P_{i} D_{i}\right) \\
& \frac{\partial T C}{\partial Q_{i}}=0 \Rightarrow Q_{i}^{*}=\sqrt{\frac{2 D_{i} C_{O_{i}}}{C_{h_{i}}}}
\end{aligned}
$$

Substituting $Q_{i}^{*}$ in TC yields:

$$
\begin{equation*}
T C^{*}=\sum_{i=1}^{n} \sqrt{2 D_{i} C_{O_{i}} C_{h_{i}}}+\sum_{i=1}^{n} P_{i} D_{i} \tag{2-81}
\end{equation*}
$$

## 2-17-2 Multiple-item EOQ model- annual number of orders the same for all

Here every time we place an order, we would like to order $n$ products; therefore the annual number of orders for all products is the same and equals:

$$
m=\frac{D_{1}}{Q_{1}}=\cdots=\frac{D_{n}}{Q_{n}}
$$

or equivalently the cycle time(T) is the same for all:

$$
T=\frac{Q_{1}}{D_{1}}=\cdots=\frac{Q_{n}}{D_{n}}
$$

In this regard two cases will be dealt with below; in one case one single order cost is paid to place an order of several items. In the other case each item has its own order cost.

## 2-17-2-1 Multiple-item EOQ Model : order cost independent of number and quantity of items

In this case we pay the order cost $\boldsymbol{C}_{\boldsymbol{O}}$ to purchase $n$ items. $\boldsymbol{C}_{\boldsymbol{O}}$ is independent of the $Q_{j}$ 's and $n$. The number of orders and the cycle time is the same for all items. The stockout is assumed not to happen. With the symbols:
$C_{h_{j}}$ The annual holding cost of product j
$\mathrm{C}_{\mathrm{o}}$ Order cost
$D_{j} \quad$ Annual demand of product \# $j$
$Q_{j}$ Order quantity of product \# j
$T=\frac{Q_{j}}{D_{j}}$, the cycle time of all items.
We could write the total cost as follows:

$$
\begin{gather*}
T C=\frac{C_{o}}{T}+\sum_{j=1}^{n} C_{h_{j}}\left(\frac{D_{j} T}{2}\right)+\sum_{j=1}^{n} P_{j} D_{j} \quad(2-81) \\
\frac{d T C}{d T}=0 \Rightarrow \\
T^{*}=\sqrt{\frac{2 C_{O}}{\sum C_{h_{j}} D_{j}}} \\
Q_{j}^{*}=T^{*} D_{j}=\frac{D_{j}}{m^{*}} \tag{2-83}
\end{gather*}
$$

It is assumed that the number of orders are the same and independent of items.

## Example 2-20

Given the annual demand, unit price and annual holding cost of each unit for 5 items in the following table, if we want to have the same number of orders for the all items and the order cost is independent of the items and equals $\$ 40.5$, find the optimal order quantity for each item.

| Item \#(j) | 1 | 2 | 3 | 4 | 5 |
| :---: | :--- | :--- | :--- | :--- | :--- |
| annual $\mathrm{D}_{\mathrm{j}}$ | 5000 | 10000 | 7000 | 15000 | 4000 |
| Pj | 6 | 5 | 3 | 4 | 6 |
| annualC $\mathrm{h}_{\mathrm{h}}$ | 1.6 | 1.4 | 0.6 | 1.15 | 1.65 |

## Solution

$$
\begin{gathered}
T^{*}=\sqrt{\frac{2 C_{O}}{\sum C_{h_{j}} D_{j}}}=\sqrt{\frac{2 \times 40.5}{5000 \times 1.6+\cdots+4000 \times 1.65}}=0.0402 \mathrm{year} \\
m^{*}=\frac{1}{T^{*}} \cong 24, Q_{1}^{*}=\frac{5000}{24}, \quad Q_{2}^{*}=\frac{10000}{24}, \quad \cdots \quad Q_{5}^{*}=\frac{4000}{24} .
\end{gathered}
$$

End of example

## Example 2-21

Two products A\&B are ordered simultaneously. The annual demand for the products are respectively $500 \& 1500$. If the annual holding cost for each unit is $\$ 10$ and cost of joint order of these two is $\$ 100$, find the optimal order quantities.

## Solution

$$
\begin{gathered}
T^{*}=\sqrt{\frac{2 C_{O}}{C_{h_{1}} D_{1}+C_{h_{2}} D_{2}}}=0.1 \mathrm{~J} \Longrightarrow m^{*}=10 \\
Q_{1}^{*}=\frac{D_{1}}{m^{*}}=\frac{500}{10}=50, \quad Q_{2}^{*}=\frac{D_{2}}{m^{*}}=\frac{1500}{10}=150
\end{gathered}
$$

## 2-17-2-1 Multiple-item EOQ Model : separate order cost for items

In this case several items are purchased simultaneously with its own order cost. The number of orders and the cycle time are the same for all items:

$$
m=\frac{D_{1}}{Q_{1}}=\frac{D_{2}}{Q_{2}}=\cdots \quad \Rightarrow \quad T=\frac{Q_{1}}{D_{1}}=\frac{Q_{2}}{D_{2}}=\cdots
$$

Substituting these relationships into
$T C_{j}=C_{O_{j}} \frac{D_{j}}{Q_{j}}+C_{h_{i}} \frac{Q_{i}}{2}+P_{j} D_{j}$ yields:
$T C_{j}=C_{O_{j}}\left(\frac{1}{T}\right)+C_{h_{j}} \frac{D_{j} T}{2}+P_{j} D_{j} \quad j=1,2,3, \ldots$
Since $T C=\sum T C_{j}$ Then:

$$
\begin{gather*}
T C=\sum_{j=1}^{n} C_{O_{j}}\left(\frac{1}{T}\right)+\sum_{j=1}^{n} C_{h_{j}} D_{j} \frac{T}{2}+\sum_{j=1}^{n} P_{j} D_{j}  \tag{2-84}\\
T^{*}=\sqrt{\frac{2 \sum C_{O_{j}}}{\sum C_{h_{j}} D_{j}}}  \tag{2-85}\\
Q_{j}^{*}=D_{j} T^{*} \tag{2-86}
\end{gather*}
$$

2-18 Deterministic continuous \& periodic review Models
In deterministic models sometimes we encounter deterministic FOS and FOI models. They are briefly introduced below.

## 2-18-1 Deterministic continuous review=deterministic (r,Q) Model= Deterministic ( FOS)Model

This model deals with a system where the stock level of the product is calculated each time a product moves in or moves out the system. The demand rate for the product is fixed and deterministic; whenever the inventory reaches fixed level $\boldsymbol{r}$ an order of fixed quantity $Q$ is placed. Note that some real world inventory systems, such as the one shown in Fig. 2.22 where the demand is not fixed, could be approximated with this deterministic continuous review model.

Fig. 2-22 Approximation of a real model with (r,Q) model
The total variable cost in this system equals:

$$
\begin{equation*}
T V C=C_{o} \frac{D}{Q}+C_{h} \frac{Q}{2} \tag{2-87}
\end{equation*}
$$

## 2-18-2 Deterministic periodic review=deterministic (R,T) Model= Deterministic ( FOI)Model

The periodic review model is one of the inventory policies that reviews physical inventory at specific interval of time T and places an order with the quantity equal to the difference between the maximum level of inventory ( R ) and the current level of inventory(A) i.e.

$$
Q= \begin{cases}R-A & A<R  \tag{2-88}\\ 0 & A \geq R\end{cases}
$$

TVC in this model equals:

$$
\begin{equation*}
T V C=\frac{C_{o}}{T}+\frac{C_{h} D T}{2} . \tag{2-89}
\end{equation*}
$$

It worth mentioning that, classic EOQ and EPQ models are both FOS and FOI.

## 2-19 Inventory Models for Deteriorating Items

In the models discussed so far, the products were assumed to have long life and does not deteriorate or the deterioration rate is negligible. The items that incur a gradual loss in quality or quantity over time while in inventory are usually called deteriorating items.

There are many references which deal with deteriorating items. One could refer to references such as Bakkar(2012), Goyal \&Giri (2001), Hung(2011) to study these kind of inventory models.

## Exercises

1-(Tersine, 1994 page 141)A company needs 54000 ball bearing sets each year. Each set costs the company $\$ 40$. Annual holding cost per unit set is $\$ 9$ and each order costs $\$ 20$. Find
a) The optimal order quantity,
b) Annual number of orders,
c) the reorder point, if the lead time is 1 month.

2-(Tersine,1994 page 141)A firm needs 38000 units of a product whose unit price is $\$ 4$. Each order costs $\$ 9$. The annual carrying cost is $25 \%$ of of the unit price. There are 52 working week in a year.
a) What is the optimal order quantity for this product?
b) How much is the annual total cost of ordering the economic quantity?
c) The maximum number of inventory in the warehouse?
d) What is the average number of inventory
e) What is the interval between 2 successive orders in weeks.

3- A company buys and sells 5 items and the at the time being the places a 5 -item order at the end of each month. The order quantity for each item is one twelfths $\left(\frac{1}{12}\right)$ of the corresponding annual demand. The company intends to shift from the current FOI system to FOS system. The ordering cost per each item is $\$ 10$. The annual carrying cost of $\$ 1$ is $\$ 0.2$ ( $\mathrm{I}=20 \%$ ). Using the table below, calculate the total cost for the FOI and FOS systems. Is shifting to the FOS system economic?

| Item <br> (i) | Annual <br> demand <br> $\mathrm{D}_{\mathrm{i}}$ | Unit price <br> ( $\mathrm{p}_{\mathrm{i}}$ | Annual <br> order cost | Average cost of holding <br> inventory in FOI <br> $\left(\frac{1}{2} I \times p_{i} \times \frac{D_{i}}{12}\right.$ |
| :--- | :--- | :--- | :--- | :--- |
| 1 | 600 | 3 | $12 \times 10$ | $0.2 \times 75$ |
| 2 | 900 | 10 | 120 | $0.2 \times 375$ |
| 3 | 2400 | 5 | 120 | $0.2 \times 500$ |
| 4 | 12000 | 5 | 120 | $0.2 \times 2500$ |
| 5 | 18000 | 1 | 120 | $0.2 \times 750$ |
| sum |  |  | 600 | $0.2 \times 4200$ |

The solution is in Tersine(1994) page 277.
4-(Tersine, 1994 page 142) If a firm overestimates its annual demand by $50 \%$, calculate the ratio of the total variable cost in overestimate case to the total variable cost when the demand is not overestimated.

5-(Tersine, 1994 page 142)The annual demand for an item is 6000 units, the unit price is $\$ 15$, each order costs $\$ 25$, annual holding cost per unit $=\$ 3$, lead time is 3 weeks and there are 50 working weeks in a year. Suppose the customers agree to backordering. Each unit backordered costs $\$ 2 / \mathrm{yr}$.

What is the
a) size of economic order quantity?
b) maximum inventory level in the optimal case?
c) reorder point?
d) number of backordered units during each order cycle?

6-(Tersine, 1994 page 143)An electronics company uses 20000 particle beams each year. The supplier of the beams offers them at the following prices

| Quantity | Unit Price(\$) |
| :--- | :---: |
| $1-799$ | 11 |
| $800-1199$ | 10 |
| $1200-1599$ | 9 |
| $\geq 1600$ | 8 |

the cost of an order is $\$ 50.00$, and the holding cost is $20 \%$ of the unit value per year. Find
a)The optimal order size that minimizes for an all-unit- discount model.
b) The optimal order size in an incremental discount model.

7-If we buy a product from out of the company it costs $\$ 5$ per unit and the ordering cost is $\$ 1$ and if we manufacture it in the company it costs $\$ 4$ per unit and the setup cost is $\$ 10$. The production rate in the company is $5000 / \mathrm{yr}$. The annual holding cost of each unit is $10 \%$ of its price. If monthly demand is 100 units, what policy do you suggest:

Buy or manufacture why? What is the reorder point and the optimal quantity per order in your suggested policy?

Ans: TC in buy policy is $\$ 6034$ and in make policy is $\$ 4852$.
7-If $\mathrm{C}_{\mathrm{h}}=1$, which of the following choices are correct?
a) $\mathrm{Q}_{\mathrm{w}}$ and $T C_{W}$ both have the same quantity regardless of their dimension.
b) the quantity of $Q_{W}$ is half of that of $T C_{W}$.
c) the quantity of $\mathrm{TC}_{\mathrm{W}}$ is half of that of $\mathrm{Q}_{\mathrm{W}}$.

9-Which phrase is not correct for completing the phrase
"In classic EOQ model it is assumed that"
a) the unit shortage cost is largish
b) The products is not deteriorating
c) the demand rate probabilistic
d) There is no constraint on, space, capital and the number order runs
Ans: choice (c)
11-Suppose the annual holding cost in classic EOQ model is estimated as much $\mathrm{C}_{\mathrm{h}}^{\prime}$, while the actual value is $C_{h}$. With this assumption, Compute the the ratio of total variable cost in terms of $\mathrm{C}_{\mathrm{h}}^{\prime}$ to the optimal total variable cost (in terms of $C_{h}$ ).

12-The annual holding cost of $\$ 1$ is $\$ 0.05$, the unit price is $\$ 100$ and the product is supplied in 100-unit boxes, find the optimal order quantity(ans:200). What would be the answer if there were no constraint on order quantity.

13-The order quantity has to satisfy $\mathrm{Q}=100 \mathrm{k}$, where k is an integer i.e. $\mathrm{k}=1,2,3, \ldots$ if the annual demand is 2400 kilo gram, the annual holding cost per unit product is $\$ 5$ and the ordering cost is $C_{o}=\$ 22$, find the optimal value for k .

Hint: $Q_{W}=145$ is not a multiple of 100 ; use the following relationship:

$$
Q^{*}\left(Q^{*}-n\right) \leq Q_{w}^{2} \leq Q^{*}\left(Q^{*}+n\right) .
$$

## 14- (Tersine, 1994, page 143)

The demand in a firm is annually 3000 units. The ordering cost is a fixed cost of $\$ 250$ and holding costs are computed at $25 \%$ of unit value per year. Source A will sell the component for $\$ 10$ regardless of the order size. Source B will only accept orders of at Ieast 600 units at a unit price of $\$ 9,50$.

Source C will charge $\$ 9.00$ per item but requires a minimum order of 800 units, (a) What Quantity should be purchased and from which source? (b) What are the cost savings in comparison with the other two sources?

15-(Tersine,1994, page 143 Pr\#13)The Supplier for the firm in Problem 2 is offering a special discount and temporarily reducing the unit price of the product by $\$ 2$.
a)What lot size should the firm order to take the advantage of the discount?
b)What cost saving would result from this order?

16-The supplier in Problem 2 has decided to increase the unit price of its component from $\$ 4.00$ to $\$ 4.2$ tomorrow. If the reorder point is 1500 units and the current stock position is 2200 units,
a) What lot size Should be ordered today
b) What cost savings will be sacrificed if no special order is placed prior to the price increase?
c) If the current stock position were 1500 instead of 200, what lot size should be ordered today?

17- (Tersine, 1994, page144)A tire manufacturing plans to produce 40000 units of a special type of tire next year. The production rate is 200 tires per day, and there are 250 working days available. The set up cost is $\$ 200$ per run, and the unit production cost is $\$ 15$. If holding costs are $\$ 11.50$ per unit per year,
a) what is the economic production quantity?
b) how many production runs should be made each year?
c) If the production lead time is 5 days, what is the reorder point?

18- The current order quantity in a firm is 1000 units. Suppose customers agree to backordering. If the annual holding costs per unit is $\$ 6$ and each unit backordered costs $\$ 3 / y r$.

19- (Tersine, 1994, page144) A firm produces five products in a work center. The available information is shown in the table:

| Chapter 2 Deterministic Models |
| :--- |
| i annual <br> demand $\mathrm{p}_{\mathrm{i}}$ daily production <br> date annual <br> $\left(\mathrm{C}_{\mathrm{h}}\right)_{\mathrm{i}}$ $\left(\mathrm{C}_{\mathrm{o}}\right)_{\mathrm{i}}$ <br> 1 6000 6 300 2.1 80 <br> 2 20000 4 500 1.4 40 <br> 3 8000 6 160 1.8 100 <br> 4 8000 2 200 0.5 50 <br> 5 15000 4 200 1.5 50 |

If there are 250 working days available:
a) What is the best production cycle?
b) What is the optimum production run size for each product?
c) What is the annual demand time?

20-(Tersine,1994, page146) A firm orders eight items from the same vendor, as shown in the table. The ordering costs are $\$ 10$ per purchase order and $\$ 0.25$ per item. Carrying costs are $15 \%$ per year.
a) What is the economic order interval?
b) If the lead time is one month, what is the maximum inventory level for each item?

1

| item <br> (i) | Annual <br> Demand <br> $(\mathrm{Di})$ | Unit <br> Cost <br> $(\mathrm{pi})$ | Order <br> Cost <br> $($ Co $)$ |
| :--- | :--- | :--- | :--- |
| 1 | 175 | 1 | $\$ 175$ |
| 2 | 425 | 0.6 | 225 |
| 3 | 115 | 2.1 | 241 |
| 4 | 90 | 3 | 270 |
| 5 | 810 | 0.75 | 607 |
| 6 | 70 | 4 | 280 |
| 7 | 190 | 5 | 950 |
| 8 | 210 | 2 | 420 |
| sum |  |  |  |

21-What is the effect of the error in $\mathrm{C}_{\mathrm{h}}$ on TVC and also the effect of error in all parameters related to TVC on it?

22- In Classic EOQ, let $\frac{Q}{Q_{w}}=\beta \& \alpha=\frac{T V C(Q)}{T C_{w}}$. Show $\beta=\alpha \pm \sqrt{\alpha^{2}-1}$.
23- What happens in backordered EOQ model if $\pi \mathrm{D}>\mathrm{TC}_{\mathrm{W}} \& \hat{\pi} \neq 0$ ?
24-(Tersine,1994, page 142) Jane wants to determine the optimum amount of money to withdraw from an automatic teller machine (ATM) per transaction. The bank charges $\$ .30$ per ATM withdrawal transaction and a flat service charge of $\$ 5.00$ per month. Jane spends an average of $\$ 10.00$ per day. She figures there is a $10 \%$ chance that she will lose her wallet or be robbed in any given year. The bank pays $6 \%$ per year on checking account balances.
a) What is her optimal withdrawal amount per transaction?
b) How might the amount of Jane's withdrawals be altered if she moved to a high crime area?

## Solution

On Sat, 6/23/18, Tersine, Richard J. wrote:
Subject: Re: THe solution of a problem
To: "Hamid Bazargan"
Date: Saturday, June 23, 2018, 10:54 AM
Hamid,
The problem solution is as follows:
(a) the unit price is $\$ 1.00$; ordering cost is $\$ .30 /$ transaction; annual demand is $365(10)=$

3650; the annual
holding cost fraction is the opportunity cost fraction plus the probability of loss or . 16
(.06+.10); the fixed
service charge of $\$ 5.00$ is irrelevant in lot size determination.
optimum $\mathrm{Q}=$ sq. root $\{2(.30) 3650 / 1(.16)\}=\$ 117.00$
(b) If Jane moves to a high crime area, she may need to increase her holding cost fraction.

This would
effectively lower the optimal withdrawal amount per transaction.
Since the text materials were completed about 25 years ago, understandably they are no
longer available.
Best wishes,

## Chapter3 <br> Constrained <br> Inventory <br> Control Problems

## Chapter 3

## Constrained Inventory Control Problems

## Aims of the chapter

This chapter deal with the problems of inventory control in which some constraints on budgets, cycle time, ware house space, number of replenishments, the holding costs, etc... are considered. The chapter briefly describes the Lagrange multiplies technique and Karush-Kuhn-Tacker conditions, widely used in solving nonlinear programming problems which arises in various fields including constrained inventory control.

## 3-1 Lagrange multiplies technique and Karush-Kuhn-Tacker conditions

Lagrange multiplies technique is used for finding the extrima of a nonlinear optimization problem with equality constrains. Karush-Kuhn-Tacker conditions generalize the Lagrange method. Below some cases of the nonlinear problems are distinguished and the above techniques are described briefly. Before discussing the cases and the methods, note the following definition.

## Definition of Lagrange's function

In constrained optimization if you multiply the function of each constraint by a multiplier and add the product to the objective function, you obtain a new function which is called Lagrange function or Lagrangian.

## 3-1-1 Nonlinear optimization problems with equality constraints

Consider a constrained optimization problem, where the constraints are in equality form and their functions are continuous and differentiable. Equality constraints restrict the feasible region to points lying on some surface inside R. To solve this equality-constrained problem, Lagrange suggest to assign a variable(known as Lagrange multiplier) to each constraint. Then write the Lagrangian function. Deriving the gradient of the Lagrangian and setting it to zero and solving the simultaneous equations usually gives the answer of the equality-constrained problem. A mathematical description of is provided below.

Consider the following minimization problem, and assign a Lagragrange multiplier to each constraint:
$\min Z=f\left(x_{1}, \ldots, x_{n}\right)$
s.t.
$h_{1}\left(x_{1} \ldots x_{n}\right)=b_{1} \quad \lambda_{1}$ :Lagraqnge Multiplier
$h_{2}\left(x_{1} \ldots x_{n}\right)=b_{2} \quad \lambda_{2}$ : Lagraqnge Multiplier
$\vdots \quad \vdots$
$h_{m}\left(x_{1} \ldots x_{n}\right)=b_{m} \quad \lambda_{m}$ : Lagraqnge Multiplier
The Lagrangian is as follows:
$L=f\left(x_{1} \cdots x_{n}\right)+\lambda_{1}\left[h_{1}\left(x_{1} \cdots x_{n}\right)-b_{1}\right]+\cdots+\lambda_{m}\left[h_{m}\left(x_{1} \cdots x_{n}\right)-b_{m}\right]$
Set the gradient of L (partial derivates of L with respect to $\mathrm{x}_{\mathrm{j}}^{\prime} s$ and $\left.\lambda_{i}{ }^{\prime} \mathrm{s}\right)$ equal to zero:
$\begin{cases}\frac{\partial L}{\partial x_{j}}=0 & j=1, \ldots, n \\ \frac{\partial L}{\partial \lambda_{i}}=h_{i}-b_{i}=0 & i=1, \ldots, \mathrm{~m}\end{cases}$
The feasible points where the partial derivatives of $L$ are simultaneously zero are the optimal point of function L , and usually

Chapter 3 Constrained Inventory Control Problems 132
provide the solution for the above equality-constrained problem(Winston, 1994 page 684).

In fact the above simultaneous equations which could written as follows:

$$
\left\{\begin{array}{l}
\nabla_{X} f(x)+\sum_{i=1}^{m} \lambda_{i} \nabla_{X} h_{i}(x)=0 \\
b_{i}-h_{i}(x)=0
\end{array}\right.
$$

are the necessary conditions for optimality and under proper convexity assumptions they are also sufficient. In Eq. (3-1) $\nabla_{x} f$ denotes the gradient of function $f$ i.e. partial derivatives of $f$ with respect to variables $\mathrm{x}_{\mathrm{j}}{ }^{\prime} s$.

In the above problem, if all functions are differentiable and continuous, $f$ is convex, $\mathrm{h}_{\mathrm{i}}$ 's are convex[e.g. linear] then the solution to Eq. (3-1) \& (3-2) is always the solution to the above optimization problem(extracted from Winston, 1994 page 685). Therefore for solving such a problem, set the derivatives of the lagrangian with respect to $\mathrm{x}_{\mathrm{j}}, \lambda_{i}$ equal to zero; then find the solution to the simultaneous equations. If The answers to $\lambda_{i}{ }^{\prime} s$ are specific numbers, then the answers to $\mathrm{x}_{\mathrm{j}}$ 's constitute the optimal solution of the optimization problem under consideration.

It is worth knowing that Eq. $(3-1) \&(3-2)$ are some times called Karush-Kuhn-Tucker\{KKT) conditions for the aforementioned equality-constrained problem.

## Example 3-1

Write the Lagrangian and KKT conditions for the following problem:
Min $Z=2 x_{1}+2 x_{2}^{2}$
s.t.

$$
\begin{aligned}
& 4 x_{1}-x_{2}=6 \\
& x_{1}, x_{2} \quad \text { unrestricted in sign }
\end{aligned}
$$

## Solution

The Lagrangian is
$\mathrm{L}=2 x_{1}+2 x_{2}^{2}+\lambda\left(4 x_{1}-x_{1}-6\right)$
KKT conditions :

$$
\begin{aligned}
& \left\{\begin{array}{c}
\nabla_{X} L(x)=\nabla_{X} f+\sum_{i=1}^{m} \lambda_{i} \nabla_{X} h_{i}(x)=0 \\
b_{i}-h_{i}(x)=0 \quad i=1, \ldots, m
\end{array}\right. \\
& \left\{\begin{array}{c}
\binom{2+4 \lambda}{4 \mathrm{x}_{2}-\lambda}=0 \\
4 \mathrm{x}_{1}-\mathrm{x}_{2}=6
\end{array} \Rightarrow \mathrm{x}_{1}=1.4688, \mathrm{x}_{2}=-0.125, \lambda=-0.5\right. \text {, }
\end{aligned}
$$

$\mathrm{x}_{1}=1.4688, \mathrm{x}_{2}=-0.125$ could be the optimal point . Since all functions of the problem are continuous and differentiable; furthermore f is convex and the function in the constraint is linear, therefore
$\mathrm{x}_{1}=1.4688, \mathrm{x}_{2}=-0.125$ is the optimal solution to the problem.

## 3-1-2 optimization of nonlinear problems with in-equality constraints

In minimization problems with constraints of type inequality, assign a variable known as Lagrange multiplier to each constraint and write the Lagrangian function and the KKT conditions as will be shown. If the answer to the KKT conditions is a feasible solution for the problem, it might also be an optimal solution to the problem. To illustrate this case consider a problem with following form:

$$
\min Z=f\left(x_{1}, \ldots, x_{n}\right)
$$

s.t.

$$
\begin{array}{lc}
g_{1}\left(x_{1} \ldots x_{n}\right) \leq b_{1}^{\prime} & \theta_{1:} \text { Lagrange Multiplier } \\
g_{2}\left(x_{1} \ldots x_{n}\right) \leq b_{2}^{\prime} & \theta_{2}: \text { Lagrange Multiplier } \\
\vdots \quad \vdots & \\
g_{m}\left(x_{1} \ldots x_{n}\right) \leq b_{m}^{\prime} & \theta_{m}: \text { Lagrange Multiplier }
\end{array}
$$

Suppose all the functions are continuous and differentiable; the constraints are of the type $g_{i} \leq b_{i}^{\prime}$ any other form has to be converted to this form even though the right had side becomes negative.

The Lgrangian is as follows:

$$
L=f\left(x_{1} \cdots x_{n}\right)+\theta_{1}\left[g_{1}\left(x_{1} \cdots x_{n}\right)-b_{1}^{\prime}\right]+\cdots+\theta_{m}\left[g_{m}\left(x_{1} \cdots x_{n}\right)-b_{m}^{\prime}\right]
$$

The optimal solution of $L$ satisfies the following conditions known as the Karush-Kuhn-Tucker $\{\mathrm{KKT}$ ) conditions:

$$
\left\{\begin{array}{l}
\nabla_{X} L=\cdot \text { or } \nabla f+\theta_{\uparrow} \nabla g_{,}+\theta_{r} \nabla g_{r}+\ldots . .=\text { or } \frac{\partial L}{\partial x_{j}}=\cdot j=1, . ., n \\
\text { or } \\
\frac{\partial f}{\partial x_{j}}+\theta_{1} \frac{\partial g_{1}}{\partial x_{j}}+\ldots+\theta_{m} \frac{\partial g_{m}}{\partial x_{j}}=\cdot \quad j=1, . ., n \\
\theta_{i}\left[b_{i}^{\prime}-g_{i}\left(x_{1}, \ldots, x_{n}\right)\right]=\cdot \quad i=1, . ., m \\
\theta_{i} \geq \cdot \quad i=1, \ldots, m
\end{array}\right.
$$

In many cases ${ }^{1}$ any point $\left(\mathrm{x}_{1}{ }^{*} \ldots \mathrm{X}_{\mathrm{n}}{ }^{*}, \theta_{1}{ }^{*}, \ldots, \theta_{\mathrm{n}}{ }^{*}\right)$ which satisfies the above conditions as well as the constraints, is the optimal solution to the aforementioned optimization problem. Note that since $g_{i}\left(x_{1} \ldots x_{n}\right) \leq b^{\prime}{ }_{i}$ is equivalent to $g_{i}\left(x_{1} \ldots x_{n}\right)+S_{i}=b^{\prime}{ }_{i}, S_{i} \geq 0$; then $\theta_{i}\left[b_{i}^{\prime}-g_{i}\left(x_{1}, \ldots, x_{n}\right)\right]=0$ and $\theta_{i} S_{i}=0$ are equivalent.

[^5]
## 3-1-3 Nonlinear optimization problems with equality and in-equality constraints

When a nonlinear optimization problem has inequality constraints of type $\leq$ and equality constraints:
$\min Z=f\left(x_{1}, \ldots, x_{n}\right)$
s.t.
$g_{i}\left(x_{1} \ldots x_{n}\right) \leq b_{i}^{\prime} \quad i=1, \ldots, \quad \theta_{i}$ : Lagrange Multiplier
$h_{j}\left(x_{1} \ldots x_{n}\right)=b_{j} \quad j=1, \ldots, \quad \lambda_{j}:$ Lagrange Multiplier
The Lgrangian :

$$
L=f\left(x_{1} \cdots x_{n}\right)+\theta_{1}\left[g_{1}\left(x_{1} \cdots x_{n}\right)-b_{1}^{\prime}\right]+\cdots+\lambda_{1}\left[h_{1}\left(x_{1} \cdots x_{n}\right)-b_{1}\right]+\ldots
$$

If all the functions are continuous and differentiable, the necessary optimality conditions, according to Karush, Kahn and Tacker would be (Bazaraa,et al 2006 page205):
$\begin{cases}\nabla f(x)+\theta_{1} \nabla g_{1}(x)+\theta_{2} \nabla g_{2}(x)+\ldots .+\lambda_{1} \nabla h_{1}(x)+\lambda_{2} \nabla \mathrm{~h}_{2}(x)+\ldots . . & 0 \\ \theta_{i}\left[b_{i}^{\prime}-g_{i}(x)\right]=0 & i=1, \ldots m \\ \theta_{i} \geq 0 & (3-7) \\ \end{cases}$
If a point wants to be optimal for the above-mentioned nonlinear optimization problem, it has to satisfy the KKT conditions as well the constraints (whether equality or non-equality).

In a problem is of the above form(minimization with both equality and non-equality ( $\leq$ constraints), the optimal values obtained for the Lagrange multipliers of equality constraint could be negative, zero or positive numbers; however for the constraint of $\leq$ type, the corresponding Lagrange multipliers must be non-negative. In other words if the optimal value is negative the KKT conditions are not satisfied. For more details on KKT conditions refer nonlinear programming text books.

## Example 3-2

Solve the following problem:
$\min f(\mathbf{x})=x_{1}\left(x_{1}-30\right)+x_{2}\left(2 x_{2}-50\right)+3 x_{1}+5 x_{2}+10 x_{3}$ s.t.

$$
\begin{gathered}
x_{1}+x_{2} \leq x_{3} \quad \text { or } \quad g_{1}\left(x_{1}, x_{2}, x_{3}\right)=x_{1}+x_{2}-x_{3} \leq 0 \\
x_{3} \leq 17.25 \quad \text { or } \quad g_{2}=x_{3}-17.25 \leq 0
\end{gathered}
$$

## Solution

## With Lingo:

model:
$\min =\mathrm{x} 1 *(\mathrm{x} 1-30)+\mathrm{x} 2 *(2 * \mathrm{x} 2-50)+3 * \mathrm{x} 1+5 * \mathrm{x} 2+10 * \mathrm{x} 3$;
$\mathrm{x} 1+\mathrm{x} 2<=\mathrm{x} 3$;
$\mathrm{x} 3<=17.25$;
$\mathrm{x} 1>=0$;
x2>=0;
$x 3>=0$;
end

Solve Menu:

$$
\text { Rows }=6 \quad \text { Vars }=3 \quad \text { No. integer vars }=0
$$

Nonlinear rows= 1 Nonlinear vars= 2 Nonlinear constraints= 0
Nonzeros= 11 Constraint nonz= 7 Density $=0.458$
Optimal solution found at step: 6
Objective value: $\quad-225.3750$

| Variable | Value | Reduced Cost |
| :---: | :---: | :---: |
| X1 | 8.500000 | 0.0000000 |
| X2 | 8.750000 | 0.0000000 |
| X3 | 17.25000 | 0.0000000 |

The second way to solve the problem is to write the KKT conditions:

Let $\mathbf{x}=x_{1}, \ldots, x_{n}$; The KKT conditions are:

$$
\left\{\begin{array}{l}
\nabla f(\mathbf{x})+u_{1} \nabla g_{1}(\mathbf{x})+u_{2} \nabla g_{2}(\mathbf{x})=0 \\
u_{i}\left[b_{i}^{\prime}-g_{i}(\mathbf{x})\right]=0 \\
u_{i} \geq 0
\end{array} \quad i=1,2\right.
$$

Or

$$
\begin{aligned}
& \left(\begin{array}{l}
\left(\begin{array}{l}
2 x_{1}-30+3 \\
4 x_{2}-50+5 \\
10
\end{array}\right)+u_{1}\left(\begin{array}{c}
\nabla g 1 \\
1 \\
-1
\end{array}\right)+u_{2}\left(\begin{array}{l}
\nabla g 2 \\
0 \\
1
\end{array}\right)=0 \\
u_{1}\left(-x_{1}-x_{2}+x_{3}\right)=0 \\
u_{2}\left(17 / 25-x_{3}\right)=0 \\
u_{1} \geq 0 \\
u_{2} \geq 0
\end{array}\right. \\
& \text { or }\left\{\begin{array}{l}
2 x_{1}-30+3+u_{1}=0 \\
4 x_{2}-50+5+u_{1}=0 \\
10-u_{1}-u_{2}=0 \\
u_{1}\left(-x_{1}-x_{2}+x_{3}\right)=0 \\
u_{2}\left(17.25-x_{3}\right)=0 \\
u_{1} \geq 0 \\
u_{2} \geq 0
\end{array}\right.
\end{aligned}
$$

To try to solve the above simultaneous equations, notice that $u_{1}$ is either 0 or 1 and therefore $2^{m}$ possible cases are identified for ( $u_{1}$, $\ldots, u_{m}$ ) where $m$ is the number of constraints; in this case $m=2$ and the four possible cases are: $\left(u_{1}=0, u_{2}=0\right),\left(u_{1}=0, u_{2}>0\right) ،\left(u_{1}>0, u_{2}=0\right)$ and $\left(u_{1}>0, u_{2}>0\right)$.

Now let consider start with case $\left(u_{1}=0, u_{2}=0\right)$
I) $u_{1}=0 \quad u_{2}=0 \quad E q \cdot(3) \Rightarrow 10-0+0=0$ impossible $\begin{array}{lll}\text { II) } u_{1}=0 & u_{2}>0 & \text { (3) } \Rightarrow 10-0+u_{2}=0 \Rightarrow u_{2}=-10 \text { unacceptable }\end{array}$

III ) $u_{1}>0 \quad u_{2}=0$

$$
\begin{aligned}
& \text { (3) } \Rightarrow 10-u_{1}=0 \Rightarrow \quad u_{1}=10 \\
& \text { (1) } \Rightarrow x_{1}=8.5 \\
& \text { (2) } \Rightarrow x_{2}=8.75 \\
& \text { (4) } \Rightarrow 10(-8.5-8.75+1.3)=0 \Rightarrow x_{3}=17.25
\end{aligned}
$$

This point satisfies the constraints. Therefore $\bar{x}=(8.5,8.75,17.25)$ is a feasible point with acceptable Lagrange multipliers. Therefore is a KKT point.
There is no need to investigate the case ( $u_{1}>0 \quad u_{2}>0$ ), because we have come up with the solution to the problem.

## 3-1-4 Nonlinear optimization problems inequality constraints and nonnegative $\boldsymbol{x}_{\mathrm{j}}{ }^{\prime}$ s

The Karush-kahn Tacker conditions for the case where we have non-negative variables as well as inequality constraints are given in references such as Wiston(1994) page 694. Needless to say if one finds the KKT point of the problem, ignoring the nonnegativity, and the point is nonnegative, the point is a KKT point for the problem having non-negative variables.

## 3-1-5 Interpretation of Lagrange multiplies

In the subject of inventory control, positive Lagrange multiplier could be interpreted as shadow price of the resources(invested capital, warehouse space, number of orders, etc). In minimization problems, the shadow price is the amount of reduction in the objective function, when the right-hand side value of the corresponding constraint increases by one unit. Of course If the objective function is TVC,this is valid until the TVC reaches $\mathrm{TC}_{\mathrm{W}}$

## 3-2 Constraint in inventory systems

In this section, We have several products and there are some constraints on the budget, warehouse space, number of orders or machine setups, maximum inventory and the cycle time, etc.
$\min Z=f(Q)$
s.t.
$g_{1}(Q) \leq 0$
$g_{m}(Q) \leq 0$
$Q=\left(Q_{1}, \mathrm{Q}_{2}, \ldots\right) \geq 0$

## A solution method

A method for solving these kind of problem is as follows:
Solve the problem as if is there is no constraint. If the calculated $\mathrm{Q}_{\mathrm{jw}}$ 's satisfy the constraints, you have come up with the Solution to the constrained problem; otherwise the constraint which is not satisfied is called active and KKT conditions is used for finding the solution to the problem.

The Lagrangian function (i.e. the objective function together with the constraint's function times the Lagrange multiplier) is as follows:

$$
\mathrm{L}=\mathrm{f}\left(Q_{1} \ldots Q_{n}\right)+\sum_{\mathrm{i}=1}^{\mathrm{m}} \theta_{i} g_{i}\left(Q_{1} \ldots Q_{n}\right)
$$

The point(s)that minimize L,satisfy the following conditions kown as KKT conditions:

$$
\left\{\begin{array}{l}
\nabla_{Q} L=0 \\
\theta_{i}\left[g_{i}\right]=0 \quad i=1, \ldots, \mathrm{~m} \\
\theta_{i} \geq 0
\end{array}\right.
$$

Note that in writing $L$, the non-negativity of the variables $\left(Q_{j} \geq 0\right)$ was not included, instead the $Q_{j}$ 's obtained from the KKT conditions have to be checked for their non negativity and feasibility and the obtained $\theta_{i}$ 's have to be nonnegative $\left(\theta_{i} \geq 0\right)$. A few cases will follow to illustrate solving constrained inventory problems.

## 3-2-1 Constraint on the space or surface of the warehouse

Suppose we have $n$ products. The order quantity of Product \# j is $\mathrm{Q}_{\mathrm{j}}$ and
each unit of the product occupy $f_{j}$ of the space or the surface area of our warehouse. If the maximum available space or surface area is F , then $\sum_{j=1}^{n} f_{j} Q_{j} \leq F$. We want to determine the order quantity $\mathrm{Q}_{\mathrm{j}}$ in such a way that total cost is minimized and the constraint is satisfied.
$\operatorname{Min} \sum_{j=1}^{n}\left(\frac{\operatorname{Co}_{j} D_{j}}{Q_{j}}+\frac{C h_{j} Q_{j}}{2}\right)$
s.t. $\sum_{j=1}^{n} f_{j} Q_{j}-F \leq 0 \quad, \quad Q_{j} \geq 0$

If the order quantities calculated from Wilson formula ( $\mathrm{Q}_{\mathrm{jw}}$ 's) satisfy the constraint, they are the optimal solution to the constrained problem; otherwise , using, the Lagrange multipliers technique, Lagrangian function is formed:
$L=\sum_{j=1}^{n}\left(\frac{\operatorname{Co}_{j} D_{j}}{Q_{j}}+\frac{\operatorname{Ch}_{j} Q_{j}}{2}\right)+\theta\left(\sum_{j=1}^{n} f_{j} Q_{j}-F\right)$
where $\theta \geq 0$ is the multiplier assigned to the constraint.
$Q_{j}^{\prime} s$, as well as feasibility, must satisfy the following KKT conditions:
$141 \quad$ Classical Topics in inventory Control

$$
\left\{\begin{array}{l}
\frac{\partial L}{\partial Q_{j}}=0 \quad \Longrightarrow Q_{j}^{*}=\sqrt{\frac{2 C o_{j} D_{j}}{C h_{j}+2 \theta f_{j}}} \quad j=1, \ldots, n \\
\theta\left(F-\sum_{j=1}^{n} f_{j} Q_{j}\right)=0 \quad j=1,2, . ., n \\
\quad \theta \geq 0
\end{array}\right.
$$

After finding the optimal $\theta, Q_{j}{ }^{*} j=1, \ldots, n$, are obtained.
If the model is of the following form:

$$
\begin{gathered}
\operatorname{Min} \sum_{j=1}^{n}\left(\frac{C o_{j} D_{j}}{Q_{j}}+\frac{C h_{j} Q_{j}}{2}\right) \\
\text { s.t. } \\
\sum_{j=1}^{n} f_{j} Q_{j}-F=0, \\
Q_{j} \geq 0 \quad \mathrm{j}=1,2, \ldots
\end{gathered}
$$

To find the optimal values of $Q_{j}$, set the gradient of $L$ equal to zero i.e. differentiate L with respect to $Q_{j}, j=1,2, \ldots$ and $\theta$; set the results equal to zero

$$
\begin{aligned}
& \nabla L=0 \equiv \\
& \left\{\begin{array}{l}
\frac{\partial L}{\partial Q_{j}}=0 \rightarrow \\
\frac{\partial L}{\partial \theta}=0 \rightarrow \\
\begin{cases}\frac{\partial L}{\partial Q_{j}}=0 \rightarrow-\frac{C o_{j} D_{j}}{Q_{j}^{2}}+\frac{C h_{j}}{2}+\theta f_{j}=0 \Rightarrow=\frac{C h_{j}+2 \theta f_{j}}{2} \Rightarrow Q_{j}=\sqrt{\frac{2 C o_{j} D_{j}}{C h_{j}+2 \theta f_{j}}} \quad j=1,2, \ldots \\
\frac{\partial L}{\partial \theta}=0 & \rightarrow \sum_{j=1}^{n} f_{j} Q_{j}-F=0\end{cases}
\end{array} \begin{array}{l}
\quad
\end{array}\right.
\end{aligned}
$$

Solve the resultant equations for the $\mathrm{Q}_{\mathrm{j}}$; insert $\mathrm{Q}_{\mathrm{j}}{ }^{\prime} \mathrm{S}$ in
$\sum_{j=1}^{n} f_{j} Q_{j}-F=0$ to find the optimal value of $\theta$.

$$
\Rightarrow\left\{\begin{array}{l}
Q_{j}=\sqrt{\frac{2 C o_{j} D_{j}}{C h_{j}+2 \theta f_{j}}} \quad j=1,2, . ., n \\
\sum_{j=1}^{n} f_{j} Q_{j}=F
\end{array}\right.
$$

This value of $\theta$ easily gives the numerical value of $Q_{j}{ }^{*}$.

## Example 3-3

The maximum available space for keeping five products in a warehouse is $2000 \mathrm{~m}^{3}$. Using the information in the following table, calculate the optimum order quantity for each product. The annual holding cost of 1 dollar is approximately $\$ 0.2$.

| Product <br> No.(j) | Annual <br> demand <br> $\left(\mathrm{D}_{\mathrm{j}}\right)$ | price <br> $\left(\mathrm{P}_{\mathrm{j}}\right)$ | Unit space <br> requirement in <br> $m^{3}\left(\mathrm{f}_{\mathrm{j}}\right)$ | $\mathrm{Co}_{\mathrm{j}}$ |
| :---: | :---: | :---: | :---: | :---: |
| 1 | 600 | 3 | 1 | 10 |
| 2 | 900 | 10 | 1.5 | 10 |
| 3 | 2400 | 5 | 0.5 | 10 |
| 4 | 1200 | 5 | 2 | 10 |
| 5 | 1800 | 1 | 1 | 10 |

## Solution

The model is as follows:

$$
\operatorname{Min} Z=\sum_{j=1}^{5}\left(\frac{C_{o} D_{j}}{Q_{j}}+\frac{I P_{j} Q_{j}}{2}\right)
$$

s.t.

$$
\begin{aligned}
& \sum f_{j} Q_{j} \leq 2000 \\
& Q_{j} \geq 0
\end{aligned}
$$

If we calculate $\mathrm{Qw}_{\mathrm{j}}, \mathrm{j}=1, \ldots, 5$ from Wilson formula, we will niotice that these order quantities do not satisfy the constraint; then we
proceed with Lagrange multiplies. Assigning $u$ as a multiplier to the constraint, we have:

$$
L=\sum_{j=1}^{5}\left(\frac{C o_{j} D_{j}}{Q_{j}}+\frac{I P_{j} Q_{j}}{2}\right)+\mathrm{u}\left(\sum_{j=1}^{5} f_{j} Q_{j}-2000\right)
$$

The KKT conditions are as follows:
$\left\{\begin{array}{l}\frac{\partial L}{\partial Q_{j}}=0 \rightarrow Q_{j}=\sqrt{\frac{2 C o_{j} D_{j}}{C h_{j}+2 u f_{j}}} \\ \mathrm{u}\left(2000-\sum f_{j} Q_{j}\right)=0 \\ u \geq 0\end{array}\right.$

$$
Q_{1}=\sqrt{\frac{2(10)(600)}{(0.2 * 3)+2 u * 1}}, \cdots, Q_{5}=\sqrt{\frac{2(10)(18000)}{(0.2 * 1)+2 u * 1}}
$$

Since $u\left(2000-\sum f_{j} Q_{j}\right)=0$, either both are zero or one of them is zero;
and since $\mathrm{u} \geq 0 \mathrm{n}$ it is possible that

1) $u=0$ and $\left(2000-\sum f_{j} Q_{j}\right)$ is nonzero,
2) $u>0$ and $\sum f_{j} Q_{j}-2000=0$,
3) both are zero.

In cases $1 \& 3$,where $u=0, Q_{j}=\sqrt{\frac{2 \mathrm{Co}_{j} \mathrm{D}_{j}}{\mathrm{Ch}_{j}+2 u f_{j}}}$ converts to Wilson formula, and hence unacceptable. Then necessarily:
$\mathrm{u}>0$ and $\sum \mathrm{f}_{\mathrm{j}} \mathrm{Q}_{\mathrm{j}}-2000=0$. Substituting $Q_{1}, \ldots, Q_{5}$ yields an equation whose variable is $u$. The equation could be solved by trial and error or fzero command in matlab:

```
Chapter 3 Constrained Inventory Control Problems 144
fzero(@(u) 2000-(1*sqrt(2*10*600)/(.2*3+2*u*1)+
1.5*sqrt(2*10*900)/(.2*10+2*u*1.5)+0.5*sqrt(2*10*2400)/(.2*5+2*u*0.5)
+2*\operatorname{sqrt}(2*10*12000)/(.2*5+2*u*2) +1*\operatorname{sqrt}(2*10*18000)/(.2*1+2*u*1)),0.1)
gives }\textrm{u}=0.1674\mathrm{ .
    Trial and error:
    clc;d=0:.0001:.21;D=1000000000;i=1;
    while abs(D)>= d(i);
        for u=0:0.0001 :0.2;
            D=2000-(1*sqrt(2*10*600)/..2*3+2*u*1)+
1.5*sqrt( 2*10*900)/(.2*10+2*u*1.5)+0.5*sqrt( 2* 10*2400)/(.2*5+2*u*0.5)
+2*sqrt(2*10*12000)/(.2*5+2*u*2)+1*sqrt(2*10*18000)/(.2*1+2*u*1));
            if (abs(D)<=d(i));
                break;
            end;
        end;
        i=i+1;
    end;
    disp(sprintf(' u= %6.4f D= %5.4f',u,d(i-1) ));
    gives u=0.1674\cong 0.17.
\(\mathrm{Q}_{1}, \ldots, \mathrm{Q}_{5}\) would be117,53,188,,293, 1122 approximately for this value of \(u\), which satisfy the constraint.
```

Interpretation of $\mathbf{u}=0.17$ : If one unit is added to the right hand side of the constraint(in this case the space of the warehouse), the objective function of the minimization problem (in this case the total cost) will decrease as much as $0.1674 \cong 0.17$. Of course this will be true until the function reaches its potential minimum.

## 3-2-2 Constraint on the budget

This section deals with 2 constraints related to the budget i.e.

$$
\sum_{\mathrm{j}=1}^{\mathrm{n}} \mathrm{p}_{\mathrm{j}} \mathrm{Q}_{\mathrm{j}}=\mathrm{C} \text { and } \quad \sum_{\mathrm{j}=1}^{\mathrm{n}} \mathrm{p}_{\mathrm{j}} \mathrm{Q}_{\mathrm{j}} \leq \mathrm{C} .
$$

## 3-2-2-1 The budget for ordering is exactly C dollars

If we have C dollars budget and want to order n products with unit price $p_{j}, j=1, . ., n$, in such a way to minimize the total cost of the inventory system then the model would be
$\operatorname{Min} T V C=\sum_{j=1}^{n}\left(\frac{C o_{j} D_{j}}{Q_{j}}+\frac{C h_{j} Q_{j}}{2}\right)$
s.t.

$$
\begin{aligned}
& \sum_{j=1}^{n} P_{j} Q_{j}=C \\
& Q_{j} \geq 0
\end{aligned}
$$

Assigning Lagrange multiplier $\lambda$ to the constraint, the Lagrangian would be :
$L=\sum_{j=1}^{n}\left(\frac{C o_{j} D_{j}}{Q_{j}}+\frac{C h_{j} Q_{j}}{2}\right)+\lambda\left(\sum_{j=1}^{n} P_{j} Q_{j}-C\right)$
Since we have only equality constraint, to solve the model it is enough to solve $\Delta L=0$ or equivalently the following:

$$
\left\{\begin{array}{l}
\frac{\partial L}{\partial Q_{j}}=0 \rightarrow Q_{j}=\sqrt{\frac{2 C o_{j} D_{j}}{C h_{j}+2 \lambda P_{j}}}=\sqrt{\frac{2 C o_{j} D_{j}}{P_{j}(I+2 \lambda)}} \quad \mathrm{j}=1, \ldots, \mathrm{n} \\
\frac{\partial L}{\partial \lambda}=0 \rightarrow \sum_{j=1}^{n} P_{j} Q_{j}=C
\end{array}\right.
$$

To find the optimal $\lambda$, substitute $Q_{j}, j=1,2, \ldots, n$ from the first equations in $\sum_{j=1}^{n} P_{j} Q_{j}=C$. After finding $\lambda$, it is easy to find $Q_{j}^{\prime}$ s. It is worth mentioning that in models of this kind which have equality constraints the optimal value of the LaGrange multiplier could be negative, zero or positive.

## 3-2-2-2 The budget for ordering is less than or equal to $C$

Suppose the model is as follows:
$\operatorname{Min} T V C=\sum_{j=1}^{n}\left(\frac{C o_{j} D_{j}}{Q_{j}}+\frac{C h_{j} Q_{j}}{2}\right)$
s.t.

$$
\begin{aligned}
& \sum_{j=1}^{n} P_{j} Q_{j} \leq C \\
& Q_{j} \geq 0
\end{aligned}
$$

The optimal values of $\mathrm{Q}_{\mathrm{j}}$ must satisfy the following KKT conditions:

$$
\left\{\begin{array}{l}
\frac{\partial L}{\partial Q_{j}}=0 \mathrm{j}=1,2, \ldots, \mathrm{n} \rightarrow \quad Q_{j}=\sqrt{\frac{2 C o_{j} D_{j}}{P_{j}(I+2 \theta)}} \\
\theta\left(C-\sum_{j=1}^{n} P_{j} Q_{j}\right)=0 \\
\theta \geq 0
\end{array}\right.
$$

## Example 3-4

Three products are to be ordered simultaneously. The maximum budget available is $\$ 14000$ to order the 3 products each time. No shortage is permitted and the annual holding cost of 1 dollar is approximately $\$ 0.2$ ( $\mathrm{I}=20 \%$ ). Using the data in the table calculate the optimal value of the ordering quantities.

|  | Dj | $\mathrm{Pj}(\$)$ | $\operatorname{Coj}(\$)$ |
| :--- | :--- | :--- | ---: |
|  | 1000 | 20 | 50 |
|  | 500 | 100 | 75 |
|  | 2000 | 50 | 100 |

## Solution

The model of the problem is:

$$
\operatorname{Min} Z=\sum_{j=1}^{3}\left(\frac{C o_{j} D_{j}}{Q_{j}}+\frac{C h_{j} Q_{j}}{2}\right)
$$

s.t.

$$
\begin{aligned}
& \sum_{j=1}^{3} P_{j} Q_{j} \leq 14000 \\
& Q_{j} \geq 0
\end{aligned}
$$

At the outset we solve the problem, ignoring the constraint:

$$
\begin{aligned}
& Q_{w 1}=\sqrt{\frac{2(50)(1000)}{(0.2)(20)}} \cong 158 \quad Q_{w 2} \cong 61 \quad Q_{w 3} \cong 200 \\
& \sum_{j=1}^{3} P_{j} Q_{j}=19260>14000
\end{aligned}
$$

Since these values do not satisfy the constraint, the KKT conditions are utilized:

$$
\begin{gathered}
\frac{\partial L}{\partial Q_{j}}=0 j=1,2,3 \rightarrow Q_{j}^{*}=\sqrt{\frac{2 C o_{j} D_{j}}{p_{j}(I+2 \theta)}} j=1,2,3 \\
\theta\left(14000-\sum P_{j} Q_{j}\right)=0 \\
\theta \geq 0 \\
\left\{\begin{array}{l}
Q_{1}=\sqrt{\frac{2 C o_{1} D_{1}}{p_{1}(I+2 \theta)}}=\sqrt{\frac{2(50)(1000)}{20(0.2+2 \theta)}}=\sqrt{\frac{10^{5}}{40(0.1+\theta)}}=\frac{50}{\sqrt{0.1+\theta}} \\
Q_{2}=\sqrt{\frac{2(75)(500)}{100(0.2+2 \theta)}}=\sqrt{\frac{75000}{200(0.1+\theta)}}=\frac{19.3649}{\sqrt{0.1+\theta}} \\
Q_{3}=\sqrt{\frac{2(100)(2000)}{50(0.2+2 \theta)}}=\sqrt{\frac{4 * 10^{5}}{100(0.1+\theta)}}=\frac{63.2456}{\sqrt{0.1+\theta}}
\end{array}\right.
\end{gathered}
$$

Since the product of $\theta$ and $\left(\sum P_{\mathrm{j}} \mathrm{Q}_{\mathrm{j}}-14000\right)$ is zero,
Either both are zero or only one of them is zero.
$\theta$ cannot be zero therefore $\sum P_{\mathrm{j}} \mathrm{Q}_{\mathrm{j}}-14000=0$
$\sum P_{j} Q_{j}=14000 \Rightarrow$

Chapter 3 Constrained Inventory Control Problems 148

$$
\begin{aligned}
& 20 \times \frac{50}{\sqrt{0.1+\theta}}+100 \times \frac{19.3649}{\sqrt{0.1+\theta}}+50 \times \frac{63.2456}{\sqrt{0.1+\theta}}=14000 \\
& x=\frac{1}{\sqrt{0.1+\theta}} \Rightarrow \quad x \cong 2.2955 \\
& \Rightarrow \theta=0.09 \rightarrow Q_{1}=114, Q_{2}=44, Q_{3}=145
\end{aligned}
$$

Since these $Q_{\mathrm{j}}^{\prime} s$ satisfy the constraint and the Lagrange multiplier $\theta$ in not negative, they form the optimal solution to the problem:
$Q_{1}^{*}=114 \quad, Q_{2}^{*}=44 \quad, Q_{3}^{*}=145$.
The optimal value of the total variable cost is
TVC ${ }^{*}=\$ 4064$

## Interpretation of $\boldsymbol{\theta}=\mathbf{0 . 0 9}$ :

If one unit is added to the right hand side of the constraint(in this case the space of the warehouse), the objective function of the minimization problem (in this case the total cost) will decrease as much as 0.09 . Of course this will occur until the function reaches its potential minimum.
Note that in the above 2 examples, if instead of maximum budget, the average inventory or the average budget involved with inventory were given, we would substitute $Q_{j}$ in the constraint with $\frac{Q_{j}}{2}$.

3-2-3 Constraint on the number of orders of multiple items
Sometimes there is a constraint on the number of orders that can be placed per unit time say per year i.e. $\sum_{j=1}^{n} m_{j}=\sum \frac{D_{j}}{Q_{j}} \leq \ell$. To deal with this case we suppose either the ordering cost $C_{o}$ is negligible or not negligible.

## 3-2-3-1 Constraint on annual number of orders- $C_{o}$ negligible

If there is a constraint on annual number of orders of multipleitem case and the ordering costs are negligible, then the model of the problem would be:

Min TVC $=\sum C_{h_{j}} \frac{Q_{j}}{2}+0$
s.t.

$$
\sum \frac{D_{j}}{Q_{j}} \leq \ell
$$

To determine the $Q_{j}^{\prime} s$, the Lagrange function and the KKT conditions are

Written:
$L=\sum C_{h_{j}} \frac{Q_{j}}{2}+\theta\left(\sum \frac{D_{j}}{Q_{j}}-\ell\right)$
$\left\{\begin{array}{l}\frac{\partial L}{\partial Q_{j}}=0, j=1,2, \ldots \\ \theta\left(\ell-\sum \frac{D_{j}}{Q_{j}}\right)=0 \\ \theta \geq 0\end{array} \Rightarrow\left\{\begin{array}{l}\frac{C_{h_{j}}}{2}-\frac{\theta D_{j}}{Q_{j}{ }^{2}}=0 \\ \theta\left(\ell-\sum \frac{D_{j}}{Q_{j}}\right)=0 \\ \theta \geq 0\end{array}\right.\right.$
The equality of $\theta\left(\ell-\sum \frac{D_{j}}{Q_{j}}\right)$ with zero imply that either both are zero or one of them is zero;
and since $\theta \geq 0 \mathrm{n}$ it is possible that

1) $\theta=0$ and $\left(\ell-\sum \frac{D_{j}}{Q_{j}}\right)$ is nonzero,
2) $\theta>0$ and $\sum \frac{D_{j}}{Q_{j}}-\ell=0$
3) both are zero.

Cases 1 and 3 cannot be valid, because with $\theta=0$, the first equation i.e. $\frac{C_{h_{j}}}{2}-\frac{\theta D_{j}}{Q_{j}{ }^{2}}=0$ does not hold. Therefore $\theta>0, m \sum \frac{D_{j}}{Q_{j}}-$ $\ell=0$ and the KKT conditions reduces to :

$$
\left\{\begin{array}{c}
Q_{j}=\sqrt{\frac{2 D_{j} \theta}{C_{h_{j}}}} \\
\ell-\sum \frac{D_{j}}{Q_{j}}=0 \\
\theta>0
\end{array}\right.
$$

Substituting $Q_{j}$ in the second equation, we have:

| Chapter 3 Constrained Inventory Control Problems | 150 |
| :--- | :--- |

$$
\sum D_{j} \sqrt{\frac{C_{h_{j}}}{2 D_{j} \theta}}=\ell \Rightarrow \theta^{*}=\frac{1}{2 \ell^{2}}\left(\sum_{j=1}^{n} \sqrt{D_{j} \times C_{h_{j}}}\right)^{2}
$$

$\theta^{*}$ is derived from the above relationship and $Q_{j}$ from $\mathrm{Q}_{\mathrm{j}}^{*}=$ $\sqrt{\frac{2 D_{j} \theta^{*}}{C h_{j}}}$,
whose feasibility have to be verified.

## 3-2-3-2 Constraint on annual number of orders- $C_{o}$ significant

If there is a constraint on annual number of orders of multiple-item case and the ordering cost is not negligible, then the model of the problem would be:
$\operatorname{Min}$ TVC $=\sum_{j=1}^{n}\left(\frac{C_{o} D_{j}}{Q_{j}}+\frac{C_{h_{j}} Q_{j}}{2}\right)$
s.t.

$$
\begin{gathered}
\sum_{j=1}^{n} \frac{D_{j}}{Q_{j}} \leq \ell \\
Q_{j} \geq 0
\end{gathered}
$$

Again here the order quantities calculated from Wilson formula would be answers to the problem if they satisfy the constraint. Otherwise the lagrangian function and KKT conditions has to be written as follows:

$$
\left\{\begin{array}{l}
\frac{\partial L}{\partial Q_{j}}=0, j=1,2, \ldots \\
\theta\left(\ell-\sum \frac{D_{j}}{Q_{j}}\right)=0 \\
\theta \geq 0
\end{array}\right.
$$

$$
\begin{aligned}
& L=\sum C_{h_{j}} \frac{Q_{j}}{2}+\theta\left(\sum \frac{D_{j}}{Q_{j}}-\ell\right) \\
& \left\{\begin{array}{l}
\frac{\partial L}{\partial Q_{j}}=0 \Rightarrow-\frac{C o_{j} D_{j}}{Q_{j}{ }^{2}}+\frac{C_{h_{j}}}{2}-\frac{\theta D_{j}}{Q_{j}{ }^{2}}=0 \Rightarrow \frac{D_{j} C o_{j}+\theta D_{j}}{Q_{j}{ }^{2}}=\frac{C_{h_{j}}}{2} \\
\theta\left(\ell-\sum \frac{D_{j}}{Q_{j}}\right)=0 \\
\theta \geq 0
\end{array}\right. \\
& \Rightarrow\left\{\begin{array}{l}
Q_{j}=\sqrt{\frac{2 D_{j}\left(C o_{j}+\theta\right)}{C_{h_{j}}}} \\
\theta\left(\ell-\sum \frac{D_{j}}{Q_{j}}\right)=0 \\
\theta \geq 0
\end{array}\right.
\end{aligned}
$$

$\theta\left(\ell-\sum \frac{D_{j}}{Q_{j}}\right)=0$ implies either both $\theta$ and $\left(\ell-\Sigma \frac{D_{j}}{Q_{j}}\right)$ are equal zero or one of the 2 is zero. For $\theta=0$, the value of $Q_{j}$ will convert into Wilson formula. If this $Q_{j}$ is feasible it is the answer; otherwise $\sum \frac{D_{j}}{Q_{j}}-\ell=0$. To compute the optimal values of $\theta$ substitute $Q_{j}=\sqrt{\frac{2 D_{j}\left(\mathrm{Co}_{j}+\theta\right)}{C_{h_{j}}}}, j=1,2, \ldots$ into
$\sum \frac{D_{j}}{Q_{j}}-\ell=0$. After finding the value of $\theta$, if it is positive, calculate $\mathrm{Q}_{\mathrm{j}}, j=1,2, \ldots, n$ by substituting the optimal value of.$\theta$; then check the feasibility of them, if feasible they are optimal since they satisfy KKT conditions.

## Example 3-5

Three products are to ordered by a firm. There is no stock-out cost and the annual carrying cost of $\$ 1$ is $\$ 0.20(\mathrm{I}=0.20)$. Considering
the data in the table and either of the following constraint, calculate the optimal order quantities,
a) $\sum \frac{D_{j}}{Q_{j}} \leq 25$
b) $\quad \sum \frac{D_{j}}{Q_{j}} \leq 15$.

|  | Dj | $\operatorname{Pj}(\$)$ | $\operatorname{Coj}(\$)$ |
| :--- | :--- | :--- | :--- |
|  | 1000 | 20 | 50 |
|  | 500 | 100 | 75 |
|  | 2000 | 50 | 200 |

## Solution

a)

The model of the first part of the problem is as follows:
$\operatorname{Min} Z=\sum_{j=1}^{3}\left(\frac{C o_{j} D_{j}}{Q_{j}}+\frac{C h_{j} Q_{j}}{2}\right)$
s.t.
$\sum \frac{D_{j}}{Q_{j}} \leq 25$
$Q_{j} \geq 0$
Ignoring the constraint, would yield
$Q_{w 1}=\sqrt{\frac{2(50)(1000)}{(0.2)(20)}} \cong 158, \quad Q_{w 2} \cong 61$ and $\quad Q_{w 3} \cong 282$
$\sum \frac{D_{j}}{Q_{j}}=\frac{1000}{158}+\frac{500}{61}+\frac{2000}{282}=21 \leq 25$
The above quintiles satisfy the constraint; therefore they are the answers to the first part.
b)The model for this part is
$\operatorname{Min} Z=\sum_{j=1}^{3}\left(\frac{C o_{j} D_{j}}{Q_{j}}+\frac{C h_{j} Q_{j}}{2}\right)$
$\sum_{Q_{j}}^{\substack{\text { s.t. } \\ Q_{j}}} \leq 15$
$Q_{j} \geq 0$
If the Lagrangian function and KKT conditions are written as done above at the beginning of this section to come up with the solution of the model, We have: $Q_{j}=\sqrt{\frac{2 D_{j}\left(C_{j}+u\right)}{C_{h_{j}}}}, j=1,2,3$. Since $\sum\left(D_{j} \times \frac{1}{Q_{j}}\right) \leq$ 15; therefore we have to find $u$ in such away that

$$
1000 \sqrt{\frac{4}{2000(50+\mathrm{u})}}+500 \sqrt{\frac{20}{1000(75+\mathrm{u})}}+2000 \sqrt{\frac{10}{4000(200+\mathrm{u})}}=15 .
$$

Using MATLAB command fzero:
$(1000 * \operatorname{sqrt}(4 /(2000 *(50+\mathrm{u})))+500 * \operatorname{sqrt}(20 /(1000 *(75+\mathrm{u})))+2000 * \operatorname{sqrt}(10 /(4000 *(20$ $0+\mathrm{u})$ )) ), 200)
yields $u=93.975$ which is nonnegative.
The optimal value of $Q_{j}^{\prime} s$ are obtained by substituting $u$ in
$Q_{j}=\sqrt{\frac{2 D_{j}\left(C_{j}+u\right)}{C_{h_{j}}}}$ which yields : $Q_{1}=269, Q_{2}=92, Q_{3}=343$.
It is evident that these quantities satisfy the constraint: $\sum \frac{D_{j}}{\mathrm{Q}_{\mathrm{j}}}=$ $\frac{1000}{269}+\frac{500}{92}+\frac{2000}{343}=14.98<15$, and $u$ is nonnegative; therefore the optimal answer is $Q_{1}^{*}=269, Q_{2}^{*}=92$ and $Q_{3}^{*}=343$.

Note if $u$ were negative or the quantities did not satisfy the constraint, we would conclude the problem in this case does not have optimal answer.

## 3-2-4 Constraint on the number of orders of multiple items having the same number of orders

Suppose a firm places order for several items which have the same number of orders per year. Also suppose there is a constraint on the number. In other words the goods have the same cycle time T $\left(\frac{\mathrm{Q}_{1}}{\mathrm{D}_{1}}=\cdots=\frac{\mathrm{Q}_{\mathrm{n}}}{\mathrm{D}_{\mathrm{n}}}=T\right)$ and the there is a constraint on T . This case is illustrated below.

## Example 3-6

The annual demand of 2 items, which ordered simultaneously, are 1000 and 2000 respectively. The holding cost is $\$ 2$ per year. The ordering cost is $\$ 100$. The annual number of orders must not exceed 5 times. Find the optimal order quantity of each item.

## Solution

The items have the same cycle time T and the model of the problem is as follows:

$$
\operatorname{Min} T V C=\sum_{j=1}^{2}\left(\frac{C_{o} D_{j}}{Q_{j}}+\frac{C_{h_{j}} Q_{j}}{2}\right)=\sum_{j=1}^{2}\left(\frac{C o_{j}}{T}+\frac{C_{h_{j} T D_{j}}}{2}\right)
$$

$$
\begin{aligned}
& \text { s.t. } \\
& \frac{1}{T} \leq 5, \\
& T>0
\end{aligned}
$$

Let us find the solution of the model ignoring the constraint:
$\frac{d T V C}{d T}=0 \Rightarrow$
$T=\sqrt{\frac{2 \sum C o_{j}}{C_{h_{1}} D_{1}+C_{h_{2}} D_{2}}}=\sqrt{\frac{200}{2(1000+1200)}}=0.2132$
This value of T satisfies the constraint and is optimal i.e. $T^{*}=0.2132$. Therefore:

$$
Q_{1}{ }^{*}=T^{*} D_{1}=2132, Q_{2}^{*}=T^{*} D_{2} \cong 2559
$$

## Example 3-7

The annual demand of 2 items, ordered simultaneously, are 8000 and 16000 respectively. The per unit holding cost is $\$ 5$ per year. The ordering cost is $\$ 1000$. The annual number of orders must not exceed 4 times. Find the optimal order quantity of each item.

## Solution

The items have the same cycle time T and the model of the problem is as follows:

$$
\operatorname{Min} T V C=\sum_{j=1}^{2}\left(\frac{C o_{j}}{T}+\frac{C_{h_{j}} T D_{j}}{2}\right)
$$

s.t.

$$
\frac{1}{T} \leq 4, T>0
$$

Let us find the solution of the model ignoring the constraint:
$\frac{\mathrm{dTVC}}{\mathrm{dT}}=0 \Rightarrow$
$m=\frac{1}{T}=5.47>4 \Rightarrow$ The constraint is active; and we write the Lagrangian and KKT conditions: $L=\sum_{j=1}^{2}\left(\frac{C o_{j}}{T}+\frac{I P_{j} D_{j} T}{2}\right)+\theta\left(\frac{1}{T}-4\right)$

$$
\left\{\begin{array}{l}
\frac{\partial L}{\partial T}=0 \\
\theta\left(4-\frac{1}{T}\right)=0 \\
\theta \geq 0
\end{array}\right.
$$

$\frac{\partial \mathrm{L}}{\partial \mathrm{T}}=0 \Rightarrow \mathrm{~T}=\sqrt{\frac{2 \sum \mathrm{Co}_{\mathrm{j}}+2 \theta}{\sum \mathrm{C}_{\mathrm{h}_{\mathrm{j}}} \mathrm{D}_{\mathrm{j}}}}$.
Since $\theta \geq 0$ and the second equations implies that:
$\theta=0 \quad \& \quad 4-\frac{1}{T} \neq 0 \quad$ or
$\theta=0 \quad \& \quad 4=\frac{1}{T} \quad$ or
$\theta>0 \quad \& \quad 4-\frac{1}{T}=0 ;$
$\theta$ cannot be zero because $T=\sqrt{\frac{2 \sum C o o_{j}}{\sum C_{h_{j} D_{j}}}}=0.18$ does not satisfy the constraint. Therefore $\theta>0$ and $4-\frac{1}{T}=0$.

$$
\begin{aligned}
& T=\frac{1}{4} \Longrightarrow\left\{\begin{array}{l}
Q_{1}=D_{1} T=8000 \times \frac{1}{4}=2000 \\
Q_{2}=D_{2} T=16000 \times \frac{1}{4}=4000
\end{array}\right. \\
& 4-\frac{1}{T}=0 \Longrightarrow T=\sqrt{\frac{2 \sum C_{j}+2 \theta}{\sum C_{h_{j}} D_{j}}}=\frac{1}{4} \Rightarrow \sqrt{\frac{2 \times 2000+2 \theta}{(5 \times 8000)+(5 \times 16000)}}=\frac{1}{4} \Rightarrow \\
& \theta=1750>0 .
\end{aligned}
$$

Since the Lagrange multiplier $\theta$ is not negative and $Q_{1 \&} Q_{2}$ are feasible, they could be the optimal solution.

## 3-2-5 constraint on the cycle time of classic EOQ modelsingle item

In this section we would like to consider a classic EOQ model whose cycle time is constrained i.e. $\frac{Q}{D}=T \leq T^{\prime} \quad$ or $\frac{Q}{D}-T^{\prime} \leq 0$. The model is therefore:

Min TVC $=\frac{C o D}{Q}+C_{h} \frac{Q}{2}=\frac{C o}{T}+C_{h} \frac{D T}{2}$
s.t.

$$
\mathrm{T}-T^{\prime} \leq 0 \& \mathrm{~T}>0
$$

To find the optimal value of the cycle time, $Q_{w}$ and T is calculated, if $T^{*}=\frac{Q_{w}}{D}=\sqrt{\frac{2 C o}{C h D}}<T^{\prime}, T^{*}$ is the optimal cycle time and $Q^{*}=T^{*} D$; otherwise L and KKT conditions are utilized:

$$
L=\frac{C o}{T}+\operatorname{Ch} \frac{D T}{2}+\theta\left(T-T^{\prime}\right)
$$

KKT conditions:

$$
\left\{\begin{array}{l}
\frac{\partial L}{\partial T}=0 \Rightarrow-\frac{C o}{T^{2}}+\frac{C h D}{2}+\theta=0 \\
\theta\left(T^{\prime}-T\right)=0 \\
\theta \geq 0
\end{array}\right.
$$

After getting the answer of $\theta$ and T related to the above conditions, if T is feasible and $\theta \geq 0$ then $Q^{*}=T D$

3-2-6 Constraint on the capital associated with inventory maximum in EPQ and EOQ models

The following examples show how to deal with the EOQ and EPQ model in which the monetary value of the maximum of the inventory in warehouse is constrained.

## Example 3-8

In an EOQ model, the capital devoted to the maximum inventory is restricted to $\$ 10,000,=\$ 200, \mathrm{I}=20 \%$ yearly , the unit price is $\$ 50$ and annual demand is 4000 . Find the economic order quantity and the corresponding annual total cost.

## Solution

The problem model is as follows:

$$
T C=\frac{C o D}{Q}+C_{h} \frac{Q}{2}+P D
$$

s.t.

$$
\mathrm{P} \times I_{\max } \leq 10000 \text { or } \mathrm{PQ} \leq 10000
$$

Ignoring the constraint would yield:

$$
Q_{w}=\sqrt{\frac{2 D C o}{C_{h}}}=400 \& I_{\max }^{*}=Q_{w}=400
$$

$P I_{\max }=50 \times 400>10000 \Rightarrow$ The constraint is active and 400 cannot be optimal. We use Lagrangian function and KKT conditions:

$$
L(Q, \theta)=\frac{C o D}{Q}+C_{h} \frac{Q}{2}++P D+\theta[P Q-10000]
$$

## Karush_Kahn-Tacker conditions:

$\left\{\begin{array}{l}\frac{\partial L}{\partial Q}=0 \\ \theta[(10000-P Q)]=0 \\ \theta \geq 0\end{array}\right.$
$\frac{\partial L}{\partial Q}=0 \quad \Rightarrow \quad Q=\sqrt{\frac{2 D C o}{\left(C_{h}+2 P \theta\right)}}$
$\theta$ cannot be zero because $Q=\sqrt{\frac{2 D C o}{\left(C_{h}+0\right)}}$ doesn't satisfy the constraint; therefore $\theta>0$ and $10000-P Q=0$ and KKT conditions reduces to :

$$
\begin{aligned}
& \left\{\begin{array}{l}
Q=\sqrt{\frac{2 D C o}{\left(C_{h}+2 P \theta\right)}} \\
1000-P Q=0 \\
\theta>0
\end{array}\right. \\
& 50 Q-10000=0 \Rightarrow Q=200 \Rightarrow \sqrt{\frac{2(4000)(200+\theta)}{0.2(50)+100 P}}=200 \Rightarrow \theta=0.3 .
\end{aligned}
$$

$\theta$ is positive and $Q$ satisfies the constraint therefore $Q^{*}=200$ is the answer.

The total cost for this amount of order quantity is

$$
\mathrm{TC}(\mathrm{Q}=200)=\frac{200 \times 4000}{(200)}+\frac{0.2 \times 50 \times 200}{2}+50 \times 4000=\$ 205000
$$

Interpretation of $\mathbf{u}=0.3$ : If one unit is added to the right hand side of the constraint(in, the objective function of the minimization problem (in this case the total cost) will decrease as much as 0.3 . Of course this will be true until the function reaches its minimum.

## Example 3-9

The capital associated with the maximum inventory of a product in a warehouse is restricted to $\$ 20000$. The annual demand is 4000 . The production capability rate is $R=8000$, the setup cost $\left(\mathrm{C}_{\mathrm{o}}\right)$ is 2500 dollars and the carrying cost per unit per year is $\$ 200$. Find the economic production quantity.

## Solution

The model of the problem:
Min TVC $=\frac{C o D}{Q}+C_{h} \frac{Q}{2}\left(1-\frac{D}{R}\right)$
s.t.

$$
P I_{\max }=P \times Q \times\left(1-\frac{D}{R}\right) \leq 20000
$$

Ignoring the constraint yields $Q^{*}=\sqrt{\frac{2 D C o}{C_{h}\left(1-\frac{D}{R}\right)}} \cong 633$ based on EPQ model. This answer does not satisfy the constraint; therefore we apply Lagrange multiplier technique to obtain the optimal solution of the model.

$$
L=\frac{C o D}{Q}+C_{h} \frac{Q}{2}\left(1-\frac{D}{R}\right)+\theta\left[P Q\left(1-\frac{D}{R}\right)-20000\right]
$$

## Karush_Kahn-Tacker conditions:

$$
\left\{\begin{array}{l}
\frac{\partial L}{\partial Q}=0 \\
\theta\left[20000-P Q\left(1-\frac{D}{R}\right)\right]=0 \\
\quad \geq 0
\end{array}\right.
$$

$$
\begin{aligned}
& \frac{\partial L}{\partial Q}=0 \Rightarrow \\
& \begin{aligned}
&-\frac{C o D}{Q^{2}}+\frac{C_{h}}{2}\left(1-\frac{D}{R}\right)+\theta P\left(1-\frac{D}{R}\right)=0 \Rightarrow Q \\
&=\sqrt{\frac{2 D C o}{\left(C_{h}+2 P \theta\right)\left(1-\frac{D}{R}\right)}}
\end{aligned}
\end{aligned}
$$

$\theta$ cannot be zero because $Q=\sqrt{\frac{2 D C o}{\left(C_{h}+0\right)\left(1-\frac{D}{R}\right)}}$ doesn't satisfy the constraint; therefore $\theta>0$ and $20000-P Q\left(1-\frac{D}{R}\right)=0$. KKT conditions reduces to:

$$
\begin{aligned}
& \left\{\begin{array}{l}
Q=\sqrt{\frac{2 D C o}{\left(C_{h}+2 P \theta\right)\left(1-\frac{D}{R}\right)}}=\sqrt{\frac{2 * 2500 * 4000}{(100+400 \times \theta)\left(1-\frac{4000}{8000}\right)}}=\sqrt{\frac{400000}{1+4 \theta}} \\
\quad P Q\left(1-\frac{D}{R}\right)=20000 \\
\quad \theta \geq 0
\end{array}\right. \\
& P Q\left(1-\frac{D}{R}\right)-20000=0 \Rightarrow
\end{aligned}
$$

$$
200 \sqrt{\frac{400000}{1+4 \theta}}\left(1-\frac{1}{2}\right)=20000 \Rightarrow \sqrt{1+4 \theta}=\sqrt{2} \Rightarrow \theta^{*}=\frac{9}{4} \Rightarrow
$$

$$
Q^{*}=\sqrt{\frac{400000}{1+4\left(\frac{9}{4}\right)}}=200
$$

Since the multiplier $\theta$ is not negative and $Q^{*}$ is feasible, therefore $Q^{*}$ could be accepted as the optimal solution to the problem.

## 3-2-7 Multiple-constraint inventory models

Sometimes several restrictions may constrain the operation of an inventory system. In this case, at first solve the problem without considering the constraint; if the solution satisfy the constraints it is the optimal solution. Otherwise find the optimal solution move the constraints to the objective function to obtain the Lagrangian form, and writing the KKT conditions.

As an illustration suppose the monetary value of the average inventory in the warehouse and also the space available for a product are restricted; then the model and the lagrange multipliers would be:
$\operatorname{Min} T V C=\sum_{j=1}^{n}\left(\frac{\operatorname{Co}_{j} D_{j}}{Q_{j}}+\frac{I P_{j} Q_{j}}{2}\right)$

| s.t. | Lagrange <br> Multiplier |
| :--- | :---: |
| $g_{1}=\sum P_{j} \frac{Q_{j}}{2} \leq M$ | $\theta_{1}$ |
| $g_{2}=\sum f_{j} Q_{j} \leq F$ | $\theta_{2}$ |

If the constraints are not satisfied with the optimal solution of the unrestricted problem, KKT conditions will be written:

$$
\begin{aligned}
& \mathrm{L}=\sum_{j=1}^{n}\left(\frac{\operatorname{Co}_{j} D_{j}}{Q_{j}}+\frac{I P_{j} Q_{j}}{2}\right)+\theta_{1}\left(\sum P_{j} \frac{Q_{j}}{2}-M\right)+\theta_{2}\left(\sum f_{j} Q_{j}-F\right) \\
& \left\{\begin{array}{l}
\nabla_{Q} L=0 \text { or } \frac{\partial L}{\partial Q_{j}}=0 \quad j=1,2, \ldots, n \\
\theta_{1}\left(M-\sum P_{j} \frac{Q_{j}}{2}\right)=0 \\
\theta_{2}\left(F-\sum f_{j} Q_{j}\right)=0 \\
\theta_{1} \geq 0 \\
\theta_{2} \geq 0
\end{array}\right.
\end{aligned}
$$

After calculating $Q_{j}$ 's from $\frac{\partial L}{\partial Q_{j}}=0$ in terms of $\theta_{1} \& \theta_{2}$ and substituting in the other 2 equations, $\theta_{1} \& \theta_{2}$ and then the values for $Q_{j}$ 's are obtained. Note that if $\theta_{1} \& \theta_{2}$ are non negatives and the calculated values for $Q_{j}$ 's are feasible, they are usually optimal.

It is worth mentioning that several computer softwares easily solve constrained problems.

## Exercises

1-(Extracted from: Example 3, Tersine,1994,page 284)
A firm buys and sell 5 items. The ordering cost of each item is $\$ 10$ per order. , The holding cost is $\% 20$ per year ie. the annual holding cost of 1 dollar is $\$ 0.2$. The unit price and annual demand for each item is as follows:

| item no.(i) | annual demand $\left(D_{\mathrm{i}}\right)$ | unit price $\left(p_{\mathrm{i}}\right)$ |
| :---: | :--- | :--- |
| 1 | 600 | 3 |
| 2 | 900 | 10 |
| 3 | 2400 | 5 |
| 4 | 12000 | 5 |
| 5 | 18000 | 1 |

With continuous review system, the mean investment calculated in its optimum state(i.e. $\sum p_{i} \frac{Q_{i}^{*}}{2}$ ) with the above data is obtained equal to $\$ 3130$. Suppose the budget for this purpose is restricted to $\$ 2000$. What is the economic order if
a)The monetary value of the average inventory is $\$ 2000$
i.e. $\sum_{\mathrm{i}=1}^{5} \frac{p_{\mathrm{i}} Q_{\mathrm{i}}}{2}=2000$.

Answer in Tersine(1994) page287.
b)The monetary value of the average inventory for all items is totally $\$ 2000$.

2-(Example 5, Tersine, 1994,page 290)
The maximum space in Problem 1 is 1500 cubic feet and each unit of the 5 item occupies respectively $1,1.5,0.5,2,1$ cubic feet and also the capital for all items is restricted to $\$ 2000$ maximum. Find the economic order quantity for each item. Answer on page 291 of Tersine (1994).

3-(Asadzadeh et al. 2006)
A firm buys 3 kind of electrical circuits. The management cannot pay more than $\$ 15000$ on each order run. Annual holding cost fraction is $20 \%$; and Stockout is not permitted. Annual demand, unit price and the ordering cost for each item is given in the Table:

| Item no. | 1 | 2 | 3 |
| :---: | :--- | :--- | :--- |
| Annual Demand | 1000 | 1000 | 2000 |
| Unit price | 50 | 20 | 80 |
| Ordering cost | 50 | 50 | 50 |

Find the economic order quantity of each item
Let us take the advantage of the present time which is a divine present, and not live either in the past or in the future

## Chapter 4

## Dynamic Lot sing Techniques

## Aims of the chapter

The present chapter addresses lot sizing problem in inventory control where the demand changes considerably from 1 period to another. Several algorithms are presented for finding the best orders sizes which cover the periods in a time horizon .

## 4-1 Introduction

In the deterministic models presented in Chapter 2, such as EOQ model for purchase and EPQ for production, implicitly it was assumed that the demand is continuous and the demand rate is constant. This chapter deals with one-item cases where the demand is discrete and changes from one period to another due to factors such as changes in season, social, economical , political issues or machine maintenance. The following table is an example which shows the demand varies from one period to another but for each period is deterministic and fixed.

| period $(t)$ | 1 | 2 | 3 | 4 | 5 | 6 | $\cdots$ | $T$ |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | :--- |
| $\operatorname{demand}\left(D_{t}\right)$ | 10 | 0 | 15 | 24 | 0 | 1 | $\ldots$ | 4 |

One such case is when we would like to produce a certain amount of a product over a T-period time horizon and the production capacity in the periods are different (Zenon et al, 2003). To do this it is required to determine the number of orders and the order sizes in such a way that minimizes the ordering and holding costs, the two significant factors that are considered while determining the economic
Chapter 4 Dynamic Lot Sizing 166
order quantity for any business. For this purpose we have to determine how much to purchase or produce at the beginning of the T periods and determine the number of periods that this amount covers. Needles to say that for some periods the scheduled order size would be zero and, instead, for some the size would be more than its own requirement.

## 4-2 Dynamic Lot Sizing Problem

When in an inventory planning problem, there is period-varying determi- nestic demand for a single storable product over some finite periods and the order size changes with period, it is called dynamic lot sizing problem. This problem deals with the determination of the production or purchase plan that minimizes the total costs incurred over the planning horizon. In other words , dynamic lot sizing problem is a planning task for a multi-period time horizon to minimize the total cost of the inventory system.

The rest of this chapter describes some of the algorithms that have been proposed for these problems. Before introducing the algorithms some assumptions are needed to be explained.

## 4-2-1 Assumptions of Dynamic Lot Sizing Algorisms

The algorithms of dynamic lot sizing described in this chapter have been developed under the following assumptions( based on Chang,2001 and Tesine, 1994 page 179):

1. The time horizon is finite and the periods of the horizon are of the same time length.
2. The demand is known but varies from one period to another period.
3. The replenishment always occurs at the beginning of a period.
4. No orders are scheduled to be received at the beginning of a period in which demand is zero.
5. Orders placed at the beginning of a period are assumed to be available in time to meet the requirements .
6. The entire order quantity is delivered outright at the beginning of a period.
7. No shortages is permitted.
8. The holding(carrying) cost is applied to the inventory available at the end of periods and only to inventory held from one period to the next.
9. All variables except demand and except specified ones are assumed to be constant,
10. The manufacturer or vendor pays for the delivery cost.
11. The replenishment of raw material to the manufacturer is assumed instantly, and the quantity is the same as the production quaintity of a production period.
12. No inventory is held after the last period.

The first models for Lot sizing problem was developed in 1950s and still is being improved. For the history and more information on this model, the reader could refer to the books by Bramel and SimchiLevi (1997), Johnson and Montgomery (1974) and Silver et al. (1996).

This model see Johnson \&Montgomeri(1974), Bramel\&Simchi, Silver et al(a996)

4-2-2 Dynamic Lot Sizing Classic Model
A mathematical model for dynamic lot sizing problem in its simplest form i.e. deterministic uncapacitated single item, zero leadtime, without backlogging, is as follows:

## Symbols

T Number of periods in the planning horizon
$t \quad$ Period index; $\in\{1, . ., T\}$
$D_{t} \quad$ The quantity of demand for $t$ th period
$C_{o_{t}}$ The ordering cost for period $t$
The cost for holding one unit at the end of Period $t$; not
$\mathrm{C}_{\mathrm{h}_{\mathrm{t}}}$ necessarily the same for all periods
The planned quantity purchased or produced for the
$Q_{t} \quad$ beginning of period $t$
$I_{t} \quad$ The on-hand inventory at the end of period $t$
Zt $\quad\left\{\begin{array}{lll}1 & \text { if } & Q_{t}>0 \\ 0 & \text { if } & Q_{t}=0\end{array}\right.$
M A largish number e.g. the sum of the demands for all periods

Total variable cost:TVC $=\sum_{i=1}^{T} C_{h_{t}} I_{t}+\sum_{i=1}^{T} C_{o_{t}}$
TVC If $C_{o} \& C_{h}$ are the same for the periods, then $\mathrm{TVC}=\mathrm{C}_{\mathrm{h}} \times \sum_{\mathrm{i}=1}^{\mathrm{T}} \mathrm{I}_{\mathrm{t}}+(\mathrm{T}) \times \mathrm{C}_{\mathrm{o}}$

$$
\begin{equation*}
\operatorname{Min} \sum_{\substack{t=1 \\ \text { s.t. }}}^{T}\left(\mathrm{C}_{\mathrm{o}_{\mathrm{t}}} \times \mathrm{z}_{\mathrm{t}}+\mathrm{C}_{\mathrm{h}_{\mathrm{t}}} \times \mathrm{I}_{\mathrm{t}}\right) \tag{1}
\end{equation*}
$$

$$
\begin{equation*}
\mathrm{I}_{\mathrm{t}-1}+\mathrm{Q}_{\mathrm{t}}=\mathrm{I}_{\mathrm{t}}+\mathrm{D}_{\mathrm{t}} \quad \mathrm{t}=1,2, \ldots \mathrm{~T} \tag{2}
\end{equation*}
$$

$$
\begin{equation*}
\mathrm{Q}_{\mathrm{t}} \leq \mathrm{M} \times \mathrm{z}_{\mathrm{t}} \quad \mathrm{t}=1,2, \ldots \mathrm{~T} \tag{3}
\end{equation*}
$$

$$
\begin{equation*}
I_{t}, Q_{t} \geq 0, \quad t=1,2, \ldots T \quad z_{t} \in\{0,1\} \tag{4}
\end{equation*}
$$

In this model
Line (1)
Represents minimization of the objective function (sum of setup/order cost and holing cost). Note that when an order is placed, there will be an incurred ordering cost.

Line (2)
The inventory - balance constraints
Line (3)
States that the quantity of each order cannot exceed a level.
Line (4):
Denotes the nonnegativity of the models variables.Note that (Simchi\& Bramel,1997 page106):
the inventory can be rewritten as $I_{t}=\sum_{i=1}^{t}\left(Q_{i}-D_{i}\right)$ and therefore $I_{t}$ variables can be eliminated from the model.

In fact, the above model does a trade-off between the holding and the order/setup cost. The answer of the model is the solution to the classic dynamic problem. In this model, assuming the holding and setup/order costs do not depend on $t$, the total variable $\operatorname{cost}(\mathrm{TVC})$ is obtained from the following relationship:
$\mathrm{TVC}=\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{i}=1}^{\mathrm{T}} \mathrm{I}_{\mathrm{t}}+(\mathrm{T}) \times \mathrm{C}_{\mathrm{o}}$

## Example 4-1

Write the mathematical model for the following dynamic problem. The ordering cost is $\$ 100$ /order and the unit holding per period id $\$ 2$. The inventory at the beginning and the end of the 8 - period time horizon is zero $(\mathrm{i} 0=0 ; \mathrm{i} 8=0)$. There is no backlogging and the lead time is ignorable. Solve the model with a software:
169 Classical topics in inventory control and Planning

| Period $(\mathrm{t})$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | sum |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| demand $\left(\mathrm{D}_{\mathrm{t}}\right)$ | 10 | 25 | 15 | 40 | 30 | 0 | 5 | 10 | 135 |

## Solution:

$\operatorname{Min} 100 \sum_{\mathrm{t}=1}^{8} \mathrm{z}_{\mathrm{t}}+2 \sum_{\mathrm{t}=1}^{8} \mathrm{I}_{\mathrm{t}}$
s.t.
$\mathrm{I} 0+\mathrm{Q} 1=\mathrm{I} 1+10$;
$\mathrm{I} 1+\mathrm{Q} 2=\mathrm{I} 2+25$;
$\mathrm{I} 2+\mathrm{Q} 3=\mathrm{I} 3+15$;
$\mathrm{I} 3+\mathrm{Q} 4=\mathrm{I} 4+40$;
$\mathrm{I} 4+\mathrm{Q} 5=\mathrm{I} 5+30$;
$\mathrm{I} 5+\mathrm{Q} 6=\mathrm{I} 6+0$;
$\mathrm{I} 6+\mathrm{Q} 7=\mathrm{I} 7+5$;
$\mathrm{I} 7+\mathrm{Q} 8=\mathrm{I} 8+10$;
$\mathrm{I} 0=0 ; \mathrm{I} 8=0$;
Big $M$ is set equal to the sum of the demands.

Q7<=135*z7;
Q8<=135*z8;
$\mathrm{z}_{\mathrm{t}} \in\{0,1\} \quad \mathrm{t}=1,2, \ldots 8$
$\mathrm{Q}_{\mathrm{t}} \geq 0, \quad \mathrm{t}=1,2, \ldots 8$
$\mathrm{I}_{\mathrm{t}} \geq 0, \quad \mathrm{t}=1,2, \ldots 8$
Solution from Lingo Software:
We typed the following phrases in LINGO environment. Note that since Lingo does not accept $i(0)$, $i(1)$ denotes initial inventory at the beginning of the 8 -period time horizon and $\mathrm{i}(9)$ denote the inventory at the end of the horizon.
sets:
index 1/1..8/:z;
index2/1..9/:i;

```
Chapter 4 Dynamic Lot Sizing
            end sets
    min=100*(@ sum(index1:z))+2*(@ sum(index2:i));
    i(1)+q1=i(2)+10;
i}(2)+q2=i(3)+25;i(3)+q3=i(4)+15;i(4)+q4=i(5)+40;i(5)+q5=i(6)+30
    i}(6)+q6=i(7)+0;i(7)+q7=i(8)+5;i(8)+q8=i(9)+10;q1<=135*z(1)
    q2<=135*z(2);q3<=135*z(3);q4<=135*z(4);
    q5<=135*z(5);q6<=135*z(6);q7<=135*z(7);q8<=135*z(8);
@FOR(index1:@BIN(z));
    !@BIN(z(1));
    !@BIN( z(8));
    i}(1)=0;i(2)>=0;i(3)>=0;i(4)>=0;i(5)>=0;i(6)>=0;i(7)>=0
i}(8)>=0;i(9)=0
    q1>=0;q2>=0;q3>=0;q4>=0;q5>=0;q6>=0;q7>=0;q8>=0;
    end
    Of course there is no need to write the non- negativity of the
variables; because it is the default in Lingo.
    Lingo gives the following answer with Solve command:
    Global optimal solution found at iteration: 39
    Objective value: 480
\begin{tabular}{ccc} 
Variable & Value & Reduced Cost \\
Z1 & 1.000000 & 100.0000 \\

Q4 & 85.00000 & 0.000000
\end{tabular}
```

| 171 | Classical topics |  |  |  | in inventory co |
| :--- | :--- | :--- | :--- | :---: | :---: |
|  |  |  |  |  |  |
|  | Q5 | 0.000000 | 0.000000 |  |  |
|  | Q6 | 0.000000 | 0.000000 |  |  |
|  | Q7 | 0.000000 | 0.000000 |  |  |
|  | Q8 | 0.000000 | 0.000000 |  |  |

Assuming zero lead time, the result is as follows:

| Period $(\mathrm{t})$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | Sum |
| :---: | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Demand $\left(\mathrm{D}_{\mathrm{t}}\right)$ | 10 | 25 | 15 | 40 | 30 | 0 | 5 | 10 | 135 |
| Quantity <br> ordered ( $\mathrm{Q}_{t}$ ) | 50 | - | - | 85 | - | - | - | - | 135 |
| Invery <br> available at the <br> end of period $\left(\mathrm{I}_{\mathrm{t}}\right)$ | 40 | 15 | 0 | 45 | 15 | 15 | 10 | 0 |  |

Costs:
The software gives the optimum cost : $\sum_{\mathrm{t}=1}^{8} 100 \mathrm{z}_{\mathrm{t}}+\sum_{\mathrm{t}=1}^{8} 2 \mathrm{I}_{\mathrm{t}}=$ 480 calculated as follows:
$\gg i_{1}=40 ; i_{2}=15 ; i_{3}=0 ; i_{4}=45 ; i_{5}=15 ; i_{6}=15 ; i_{7}=10 ; i_{8}=0 ;$
$\gg \mathrm{z}_{1}=1 ; \mathrm{z}_{2}=0 ; \mathrm{z}_{3}=0 ; \mathrm{z}_{4}=1 ; \mathrm{z}_{5}=0 ; \mathrm{z}_{6}=0 ; \mathrm{z}_{7}=0 ; \mathrm{z}_{8}=0 ;$
$\gg \mathrm{TVC}=\quad 100 \quad\left(\mathrm{z}_{1}+\mathrm{z}_{2}+\mathrm{z}_{3}+\mathrm{z}_{4}+\mathrm{Z}_{5}+\mathrm{Z}_{6}+\mathrm{Z}_{7}+\mathrm{z}_{8}\right)+2$
$\left(\mathrm{i}_{1}+\mathrm{i}_{2}+\mathrm{i}_{3}+\mathrm{i}_{4}+\mathrm{i}_{5}+\mathrm{i}_{6}+\mathrm{i}_{7}+\mathrm{i}_{8}\right)$
TVC $=100(1+0+0+1+0+0+0+0)+2(140)=200+280=480$
Or according to Eq.(4-1):
$\mathrm{TVC}=C_{\mathrm{h}} \sum_{\mathrm{i}=1}^{\mathrm{T}} I_{t}+(\mathrm{T}) \times C_{\mathrm{o}}$
$\mathrm{C}_{\mathrm{o}}=200, \quad C_{\mathrm{h}}=2$
$2 \sum_{\mathrm{t}=1}^{8} \mathrm{I}_{\mathrm{t}}=2(40+15+0+45+\cdots+0)=2 \times 140=280$
TVC $=280+(2)(100)=480$. End of example

## 4-3 Model Solution Techniques

Many exact, heuristic and meta-heuristic have been proposed for solving dynamic lot sizing problems in the last decades. The answer given by Lingo software for Example $4-1$ is considered an exact solution. Among other exact solution techniques is dynamic programming(DP). One of the DP algorithms is Wagner-Within algorithm which will be discussed at the end of this chapter.

Several meta-heuristic algorithms such as Genetic Algorithm, Ant Colony, Variable Neighborhood Search have been applied to solve the dynamic lot sizing. These kind of algorithms have been discussed in references such as Zenon(2003\&2006).

## Heuristc Algorithms

This part discusses a number of heuristic approaches for finding the answer to the dynamic lot sizing model. Although the heuristic algorithms are approximate and do not give an optimal solution but some of them give good solution. It is very common in practice to use an approximate method. One reason is that the approximate methods are easy to understand. It is also easy to check the computations manually(Axsater,2015,page60).

Orlicky (1975) divides lot sizing into static and dynamic defined as follows(Yilmaz, dated-nil, page44)

Static order quantity is defined as the one that once compute, continues unchanged in the planned order schedule. A dynamic order quantity, on the other hand, is subject to continuous re-computation. According to Orlicky (1975), only The so-called Fixed order Quantity technique is always static, while others can be used for dynamic repaining at the users option
(End of quote).
Among the heuristic techniques used for solving dynamic lot sizing are the following ones:

1- Lot for Lot L4L( LFL)
2 - Fixed order quantity (FOQ)

> 2-1 Economic order Quaintly (EOQ)

3- Fixed Period Requirement (FPR) or Fixed Order Period(FOP) or Periods Of Supply (POS)algorithm

3-1 Economic Order Interval (EOI ) or Period order Quantity ( POQ)
or Fixed order Interval( FOI ) algorithm
4- Least Unit Cost (LUC) algorithm
5- Total cost (LTC) Algorithm = Part Period Algorithm (PPA)
6- Part Period Balancing (PPB) )
7- Incremental Part Period Algorithm (IPPA)
8-Silver-Meal (SM) Algorithm
As well as the above algorithms described below, there are other heuristic techniques such as Least Period Cost (LPC)method, Uniform Order Quantity (UOQ) lot sizing technique, Foris Webster, Fix - Relax method and Groff's method which have applied to solve dynamic lot sizing problems.

Axsater(2015),Tersine(1994), Peterson\& Silver(1991), Winston (1994) are among references which deal with dynamic lot sizing techniques.

4-3-1 Lot -for -Lot (LFL=L4L)method
In lot-for-lot rule or method, an order is placed for each period in which there is a non-zero demand in the exact quantity required for that period. If the lead time is zero, the quantity planned for the beginning of the period $\left(\mathbf{Q}_{\mathbf{t}}\right)$ is equal to $\mathbf{Q}_{\mathbf{t}}=\mathbf{D}_{\mathbf{t}}, \mathbf{t}=\mathbf{1}, \mathbf{2}, \ldots, \mathbf{T}$. Therefore the number of orders is large and is generally used for the products that have storage restrictions such as deteriorating products. LFL method is also suitable for high-volume continuous production (assembly lines). The lead time should be small. This ordering rule is the simplest among the dynamic ordering techniques. Although the method does not use costs for determining the amount of orders, but it is suitable for goods with high holding cost or in other words(Yilmaz, dated-nil) for goods that have a high unit price and a slight ordering cost. This technique (Yilmaz, dated-nil) minimizes the inventory holding cost.

## Example 4-2

Determine the lot sizes by LFL rule from the data below; also calculate TVC if $C_{o}=100$ and $C_{h} \cong 0 . \mathrm{T}_{\mathrm{L} \cong 0}$.

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | - | 43 | 19 | 35 | 58 | - | - | 12 |

## Solution

The second row of the following table shows the demand of each period and the third row gives the lot sizes to be placed by lot-for lot rule, assuming the lead time is zero. Rows 5 and 6 show the costs

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | sum |
| :---: | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Dt | - | 43 | 19 | 35 | 58 | - | - | 12 |  |
| $\mathrm{Q}_{\mathrm{t}}$ | - | 43 | 19 | 35 | 58 | - | - | 12 |  |
| $\mathrm{C}_{\mathrm{O}}$ |  | 100 | 100 | 100 | 100 |  |  | 100 | 500 |
| Holding <br> cost | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| TVC | 0 | 100 | 100 | 100 | 100 | 0 | 0 | 100 | 500 |

The total variable cost for this example is TVC=500.

Note that if the lead time is not zero all orders are placed before the beginning of the periods; e.g. with $\mathrm{T}_{\mathrm{L}}=1$ all orders would be placed one period ahead.

4-3-2 Fixed order Quantity (FOQ)method
In fixed order quantity rule, there is a constraint: a fixed amount or an integer multiple of it must be ordered, every time an order is placed for a particular item to be purchased or produced. The fixed quantity $(\mathrm{Q})$ depends upon the restrictions on transportation capacity, packaging, storage capacity, quantity discounts and production capacity. It is required to order the smallest multiple that is immediately greater the required demand to satisfy the demand and prevent shortage. Yilmaz points out that "this technique would be applicable to items with an ordering cost sufficiently high to rule out ordering in net requirement quantities, period by period". In this technique the order quantity is fixed but the time interval between the orders is not usually the same.

## Example 4-3

A workshop produces an item in batches of size 100. The table shows the equipments of a 10 -period horizon. Prepare a production plan for the time horizon using FOQ rule and calculate the costs if $\mathbf{C}_{\mathrm{h}}=\$ \mathbf{2}$ and the setup cost per run is $\$ 1000$.

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Dt | 20 | 50 | 10 | 50 | 50 | 10 | 20 | 40 | 20 | 30 |

## Solution

Costs:

| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Dt | 20 | 5 | 10 | 50 | 50 | 1 | 20 | 40 | 2 | 30 | 300 |
| Qt | 100 | 0 | 0 | 100 | 0 | 0 | 100 | 0 | 0 | 0 | 300 |
| $t I$ | 80 | 3 | 20 | 70 | 20 | 1 | 90 | 50 | 3 | 0 |  |

ordering cost: $3 \times \mathrm{C}_{\mathrm{o}}=3000$,
jolding cost: $\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{10} \mathrm{I}_{\mathrm{t}}=2(80+30+\cdots+30+0)=800$,
Total variable cost : TVC $=3000+800=3800$.

## Example 4-4

The following table shows the requirements schedule for the nine periods. Determine the order sizes by FOQ policy. Use lot sizes of multiples 15 . $\mathbf{T}_{\mathbf{L}} \cong \mathbf{0}$.
175 Classical topics in inventory control and Planning

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Dt | 0 | 40 | 10 | 25 | 35 | 0 | 10 | 10 | 35 |

## Solution

Third row of the following table gives the solution. The $4^{\text {th }}$ row is the inventory at the end of period $t$.

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | sum |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Dt | 0 | 40 | 10 | 25 | 35 | 0 | 10 | 10 | 35 | 165 |
| Qt | - | 45 | 15 | 15 | 45 | - | - | 15 | 30 | 165 |
| It | 0 | 5 | 10 | 0 | 10 | 10 | 0 | 5 | 0 |  |

Note:
The demands of some periods are greater than 15 ; that is why lot sizes of more than 15 were ordered.

Costs: Assuming the cost per order is $\mathbf{C}_{\mathbf{0}}$ and the unit holding cost per period is $\mathrm{C}_{\mathrm{h}}$, then
ordering cost: $6 \times \mathrm{C}_{\mathrm{O}}$
holding cost : $\mathrm{C}_{\mathrm{h}} *(5+10+0+10+10+0+5+0)=40 \mathrm{C}_{\mathrm{h}}$
$T V C=6 \mathrm{C}_{\mathrm{o}}+40 \mathrm{C}_{\mathrm{h}} \boldsymbol{\square}$

## 4-3-2-1 Economic order Quantity (EOQ) lot sizing policy

EOQ policy is a special case of FOQ policy in which the average of the demands of the periods $(\bar{D})$ is used to calculate EOQ according to Wilson Formula for purchase or production lot, if the range of demand changes is not too much. The calculated EOQ is rounded to the immediate greater integer. EOQ may not be necessarily suitable for lot size. If the EOQ does not satisfy the demand of any period, use the smallest multiple of it( $2 \times \mathrm{EOQ}, 3 \times \mathrm{EOQ}, \ldots$ ) that will avoid shortage (Winston 1994, page 947). The more the discontinuous and nonuniform the demand, the less effective the EOQ will prove to be(Yilmaz, dated-nil).

## Example 4-5

The demand for all coming 10 months is the same and equal to 25 . $\mathrm{T}_{\mathrm{L}}=0$ and the setup cost $\mathrm{Co}=\$ 80$. The unit holding cost per period is
$\mathrm{C}_{\mathrm{h}}=1.5$. Determine the order sizes by EOQ policy. What are the costs?

## Solution

$$
\text { Since EOQ }=\sqrt{\frac{2 D C_{o}}{C_{h}}}=\operatorname{sqrt}(2 * 25 * 80 / 1.5)=51.64 \text { therfore }
$$

Q is set equal to 52 and we could have the plan given in the following table.

| $Q_{w}$ <br> Error factor | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | $\ldots$ | 1 | 1.2 | 1.4 | $\ldots$ | 2 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Relative increase <br> in TVC(\%) | 405 | 160 | 81 | 45 | 25 |  | 0 | 1.7 | 5.7 | $\ldots$ | 25 |

Costs
Ordering cost: $5 \mathrm{C}_{\mathrm{o}}$
Holding cost $=\mathrm{C}_{\mathrm{h}}(27+2+\cdots+35+10)=185 \mathrm{C}_{\mathrm{h}}$

$$
\mathrm{C}_{\mathrm{h}}=1.5, \mathrm{Co}=80
$$

$\mathrm{TVC}=5 \mathrm{C}_{\mathrm{o}}+185 \mathrm{C}_{\mathrm{h}}=677.5$.
If the lot size were chosen $\mathrm{Q}=50$ then

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 25 | 25 | 25 | 25 | 25 | 25 | 25 | 25 | 25 | 25 |
| $\mathrm{Q}_{\mathrm{t}}$ | 50 | - | 50 | - | 50 | - | 50 | - | 50 | - |
| $\mathrm{I}_{\mathrm{t}}$ | 25 | 0 | 25 | 0 | 25 | 0 | 25 | 0 | 25 | 0 |

Ordering cost: $5 \mathrm{C}_{\mathrm{o}}$
Holding cost $=\mathrm{C}_{\mathrm{h}}(25+25+25+25+25)=125 \mathrm{C}_{\mathrm{h}}$ $\mathrm{C}_{\mathrm{h}}=1.5$, ‘Co $=80$
$\mathrm{TVC}=5 \mathrm{C}_{\mathrm{o}}+125 \mathrm{C}_{\mathrm{h}}=587.5$.

## 4-3-3 Fixed Order Period (FOP ) or Periods of Supply (POS) policy

In Fixed Order Period method of lot sizing, the item is ordered every T time i.e. the time interval between successive orders is a fixed time such as T, due to some restrictions. This method is also called Periods of Supply (POS) policy; and it is not necessarily economical. In this method the order size changes but the interval between successive orders is constant. In a special form of FOP called Fixed Period Requirement(FPR),the fixed T is set equal to $m$ periods and
$Q_{t}=\sum_{i=t}^{t+m-1} D_{i}$
where
m The time interval between two successive orders
(in number or periods)
$Q_{t} \quad$ The order to be received at the beginning of Period $t$
$D_{t} \quad$ The demand of period $t$

## Example 4-6

The following table shows the future monthly demands for a product. The lead time is 3 months and orders are set to exactly match the requirements of 2 months. The unit holding cost per period for all periods is equal to $\mathrm{C}_{\mathrm{h}}$. Determine the lot sizes and the costs for the time horizon by FPR rule.

| period | Sep | Oct | Nov | Dec | Jan | Feb | Mar | Apr | May | Jun |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| demand | - | - | - | 5 | 10 | 15 | 20 | 35 | 5 | 25 |

| Solution |
| :--- |
| With FPR rule: |

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{D}_{\mathrm{t}}$ | 0 | 0 | 0 |  | 10 |  |  |  |  | 25 |
| $\mathrm{Q}_{\mathrm{t}}$ |  |  |  |  |  |  |  |  | - | - |
| t | 0 |  | 0 | 10 | 0 | 20 | 0 | 5 | 0 | 0 |

ordering cost $=4 \mathrm{C}_{0}$,
holding cost $=\sum_{\mathrm{t}=1}^{10} \mathrm{C}_{\mathrm{h}} \times \mathrm{I}_{\mathrm{t}}=\mathrm{C}_{\mathrm{h}} *(10+20+5)=35 \mathrm{C}_{\mathrm{h}}$

$$
T V C=4 \mathrm{C}_{\mathrm{o}}+35 \mathrm{C}_{\mathrm{h}} \mathbf{\Delta}
$$

## Example 4-7 ${ }^{1}$

Apply POS method for the data given below. Order for 3 weeks ahead. The lead time is 2 weeks and the safety stock is 80 . The initial inventory is 370 . The unit holding cost per period is $\mathbf{C}_{\mathbf{h}}=\mathbf{1 . 5}$.

| t (week) | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 130 | 160 | 120 | 260 | 130 | 120 | 185 | 115 |

## Solution

From the initial inventory, 80 units are left after period 2. As the following table shows 2 more orders are needed:

| t <br> (TL $=2$ weeks | Initial <br> inventory | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Gross <br> Requirement(Dt) |  | 130 | 160 | 120 | 260 | 13 | 120 | 185 | 115 |
| Planned Receipts |  |  |  | 510 |  |  | 420 |  |  |
| Planned Order <br> Releases(Qt) |  | 510 |  |  | 420 |  |  |  |  |
| Projected <br> Available $\left(\mathrm{I}_{\mathrm{t}}\right)$ | 370 | 240 | 80 | 470 | 210 | 80 | 380 | 195 | 80 |

Costs:
Ordering cost: $\mathrm{C}_{\mathrm{o}} \times 2$
Holding cost :

$$
\begin{gathered}
\begin{array}{c}
\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{8} \mathrm{I}_{\mathrm{t}}=\mathrm{C}_{\mathrm{h}} *(240+80+470+210+80+380+195+80) \\
\quad=1735 \mathrm{C}_{\mathrm{h}}
\end{array} \\
\mathrm{TVC}=2 \mathrm{C}_{\mathrm{o}}+1735 \mathrm{C}_{\mathrm{h}}
\end{gathered}
$$

## 4-3-3-1 Economic Order Interval ( ${ }^{1}$ EOI) method or Period Order Quantity (POQ) or Fixed Order Interval(FOI)

In this heuristic method which is a kind of Fixed Order Period method and sometimes called Fixed Order Interval method, a fixed number of periods is used for ordering. This fixed number (T) is derived from :

$$
\begin{equation*}
\mathrm{T}=\frac{\mathrm{EOQ}}{\overline{\mathrm{D}}}=\sqrt{\frac{2 \mathrm{C}_{\mathrm{o}}}{\overline{\mathrm{D}} \times \mathrm{I} \times \mathrm{P}}} \tag{4-2}
\end{equation*}
$$

Where
$\bar{D} \quad$ The average of the period requirements
If the calculated $T=\frac{E O Q}{\bar{D}}$ is not integer, round it.. If it is possible to calculate the average inventory cost per period, from the integers ( less than or the greater than T ) choose the one with less cost. The consumption during time T is sometimes dented by POQ :

Consumption during time $\mathrm{T}=\mathrm{POQ}$.
It is worth knowing that together with a fixed number of periods, some- times another number is given as the maximum inventory in this method. If so the amount for placing an order is calculated from the difference between the maximum and the inventory available at the time of placing an order.

For more details see Tersine (1994) page 134, Peterson \&Silver(1991) page 327

Example 4-8
Apply FOI rule to the following data in order to determine the order quantities which cover the 9 -period horizon. $C_{\mathrm{o}}=\$ 100, \mathrm{~T}_{\mathrm{L}} \cong$ $0, \mathrm{P}=\$ 50, \mathrm{I}=2 \%$. The unit holding cost is the same for all periods.

[^6]| Chapter 4 Dynamic Lot Sizing |  |  |  |  |  |  |  |  | 180 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| t(month) | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| $D_{t}$ | 10 | 3 | 30 | 100 | 7 | 15 | 80 | 50 | 15 |

## Solution

$$
\bar{D}=\frac{\sum_{t=1}^{9} D_{t}}{9}=34.5 \mathrm{~g} T^{*}=\sqrt{\frac{2 C_{o}}{\bar{D} I P}}=2.41 \quad \rightarrow T^{*}=3
$$

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | sum |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 10 | 3 | 30 | 100 | 7 | 15 | 80 | 50 | 15 | 310 |
| $\mathrm{Q}_{\mathrm{t}}$ | 43 |  |  | 122 |  |  | 145 |  |  | 310 |
| $\mathrm{I}_{\mathrm{t}}$ | 33 | 30 | 0 | 22 | 15 | 0 | 65 | 15 | 0 | 180 |

If the planning for the receipt of the orders were such that the demand after the receipt of the order was zero, schedule the order for the next period with positive demand. For example if the demand of Period 4 were zero instead of 122 , the order would be scheduled for the beginning of Period 5 that has a positive demand.

Cost:
Ordering cost: $3 \mathrm{C}_{\mathrm{o}}$
Holding cost:

$$
\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{10} \mathrm{I}_{\mathrm{t}}=\mathrm{C}_{\mathrm{h}}\left(33+30+22+15+65+15=180 \mathrm{C}_{\mathrm{h}}\right.
$$

Total Variable cost
$\mathrm{C}_{\mathrm{h}}=\mathrm{I} \times \mathrm{P}=.02 \times 50=1$
$\mathrm{TVC}=3 * \mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{10} \mathrm{I}_{\mathrm{t}}=3 \times 100+(1)(180)=480$

## Example 4-9 ${ }^{1}$

The demands of the next 8 periods for a product are given in the following table. The unit price is $\$ 1.5$, the setup cost is $\mathrm{C}_{\mathrm{o}}=100$ and annual $\mathrm{I}=\% 25$ for all periods. $\mathrm{T}_{\mathrm{L}}=2$ weeks. The

[^7]initial invent- tory is 370 . Apply POQ method to determine the lot sizes. Calculate the costs, assuming the unit holding cost per period is $C_{h}$

| T(week) | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| :---: | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 130 | 160 | 120 | 260 | 130 | 120 | 185 | 115 |

## Solution

$$
\begin{aligned}
& \mathrm{C}_{\mathrm{o}}=10, \quad \mathrm{C}_{\mathrm{h}}=\frac{0.25 \times 1.50}{52} \text { per week } \\
& \overline{\mathrm{D}}=\frac{130+160+120+260+130+120+185+115}{8}=152.5 \text { per week } \\
& \mathrm{EOQ}=\sqrt{\frac{2 \overline{\mathrm{D}} \mathrm{C}_{\mathrm{o}}}{\mathrm{C}_{\mathrm{h}}}}=\sqrt{\frac{2(152.5)(10)}{\frac{0.25 \times 1.5}{52}}}=650.33 \rightarrow 650 \\
& \mathrm{~T}=\frac{\mathrm{EOQ}}{\overline{\mathrm{D}}}=\frac{650}{152.5}=4.262 \cong 4
\end{aligned}
$$

As observed from the table, the initial inventory suffices period 1 and 2. A lot of size 630 is placed for Periods 3 to 6 at the start of Period 1(note that we have a lead time of 2 weeks). To cover the Periods $7 \& 8$ a lot of size 300 is placed at the start of Period 5. Row 4 of the table shows the remaining inventory at the end of the periods; e.g. the on-hand inventory at the end of periods $3,7 \& 8$ are:

| $t$ | $t$ |
| :---: | :---: |
| $t=3$ | $I_{3}=80+630-120=590$ |
| $t=7$ | $I_{7}=80+300-185=195$ |
| $T=8$ | $I_{9}=195-115=80$ |

Chapter 4 Dynamic Lot Sizing 182

costs: $2 C_{0}$
Holding cost:
$\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{8} \mathrm{I}_{\mathrm{t}}=\mathrm{C}_{\mathrm{h}} *(240+80+590+330+200+80+195+80)=1795 \mathrm{C}_{\mathrm{h}}$
$\quad$ Total Variable cost:
$T V C=2 C_{0}+1795 \mathrm{C}_{\mathrm{h}}$

## Example 4-10

The demands for a product during the next 8 periods and the unit holding cost per period for various periods are given below:

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{D}_{\mathrm{t}}$ | 45 | 60 | 35 | 50 | 70 | 50 | 60 | 80 |
| $\mathrm{C}_{\mathrm{h}_{\mathrm{t}}}$ | 10 | 12 | 14 | 15 | 18 | 20 | 20 | 20 |

the lead time is negligible and every 2 periods an order is placed ( 2-period FOI rule). The maximum on-hand inventory is set to be 140 units and no safety stock is necessary. Find the order lot sizes in order to plan for the time horizon, Also calculate the TVC.

## Solution

Since the lead time is zero and we have a ceiling for inventory, the order quantities $\left(\mathrm{Q}_{\mathrm{t}}\right.$ 's) are obtained from the difference between the maximum i.e. 140 and the on hand inventory at the beginning of the period as shown in the table below:

| period $(\mathrm{t})$ | 1 | 2 | 3 | 4 | 5 | 6 | $\ldots$ | T |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | :--- |
| demand $\left(\mathrm{D}_{\mathrm{t}}\right)$ | 10 | 0 | 15 | 24 | 0 | 1 | $\ldots$ | 4 |

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | sum |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 45 | 60 | 35 | 50 | 70 | 50 | 60 | 80 | 450 |
| $\mathrm{Q}_{\mathrm{t}}$ | 140 | - | 140 <br> -35 <br> 105 | - | 140 <br> -55 <br> $=85$ |  | 120 | - | 450 |
| $\mathrm{I}_{\mathrm{t}}$ | 95 | 35 | 105 | 55 | 70 | 20 | 80 | 0 |  |

Ordering cost: $4 \mathrm{C}_{\mathrm{o}}$
Holding cost : $\sum_{\mathrm{t}=1}^{8}\left(\mathrm{C}_{\mathrm{h}}\right)_{\mathrm{t}} \times \mathrm{I}_{\mathrm{t}}=$
$10(95)+12 \times 35+14(105)+15(55)+18(70)+20(20)+80(20)+0$

$$
=6925
$$

$\mathrm{TVC}=4 \times \mathrm{C}_{0}+6925$

## 4-3-4 Least Unit Cost (LUC ) ${ }^{1}$ Algorithm

Supposewe would like to place an order which covers the next $i$ periods and would like to know how many periods the order should cover. Least unit cost (LUC) method is based on minimization of ordering and holding cost per unit product. This cost denoted by UC(i) $i=1,2, \ldots$ is defined as follows:

$$
\begin{aligned}
& U C(i)=\frac{\text { ordering cost }+ \text { holding cost }}{\text { The sum of demand up to ith perios }}=\frac{C_{O}+C_{h} \times \sum_{t=1}^{i}(t-1) D_{\mathrm{t}}}{\sum_{t=1}^{i} D_{t}} \\
& \begin{array}{r}
U C(i)=\frac{C_{O}+C_{h} \times \sum_{t=1}^{i-1}(t) D_{\mathrm{t}+1}}{\sum_{t=1}^{i} D_{t}} \\
\qquad=\frac{C_{O}+C_{h}\left(1 D_{2}+2 D_{3}+\cdots+(\mathrm{i}-1) D_{\mathrm{i}}\right)}{\sum_{t=1}^{i} D_{t}}
\end{array}
\end{aligned}
$$

where
i The period through the end of which the order covers
$C_{O} \quad$ Ordering cost
$C_{h} \quad$ Holding cost per unit hold at the end of period
$D_{t} \quad$ The requirement of period t

The algorithm of LUC may take several iterations to complete the planning horizon. During the process, the periods for which the planning has been performed are put away and new iterations are performed until all periods are planned.

In the first iteration the starting period is Period 1. UC(i) is consecutively calculated for the starting period and the next periods ( $\mathrm{i}=1,2, \ldots$ ) until UC(i) for a particular $i$ satisfy the following two conditions:

$$
U C(i) \leq U C(i-1)
$$

and

$$
\begin{equation*}
U C(i)<U C(i+1) \tag{4-4}
\end{equation*}
$$

Denote this i by $i_{1}$. Place an order to cover Periods 1 through $\mathrm{i}_{1}$.

For the second iteration take $i_{1}+1$ as the starting period and calculate $\operatorname{UC}(\mathrm{i})$ for $\mathrm{i}=\mathrm{i}_{1}+1, \mathrm{i}_{1}+2, \ldots$ from: $U C(i)=$ $\frac{C_{o}+C_{h} \times \sum_{\mathrm{t} \geq \mathrm{i}_{1}+1}\left(t-\left(\mathrm{i}_{1}+1\right)\right) D_{\mathrm{t}}}{\sum_{\mathrm{t} \geq \mathrm{i}_{1}+1} D_{t}}$.

The stopping criterion here is the same as that of the previous itera- tion. Denote the period satisfying Eq. $4-4$ by $\mathrm{i}_{2}$. Perform new iterations until the entire time horizon is covered.

If when increasing $i=1,2, \ldots$ in any iteration, you reach the end of the time horizon and the stopping criterion namely Eq. 4-4 is not satisfied, then stop and place the last order in such a way it cover the remaining periods of the iteration (the unplanned periods).

## Example 4-11

Find the order lot sizes for the time horizon given in the table below using LUC heuristic method. If the order cost is $\$ 100$ and the unit holding cost per period is $\$ 2$, calculate the costs.

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{D}_{\mathrm{t}}$ | 1 | 2 | 1 | 4 | 3 | 0 | 5 | 1 |

## Solution

The problem is solved by LUC method through 3 iterations; in each iteration UC(i) is consecutively computed, when UC(i) starts to increase the iteration stops and an order is placed for the sum of the requirements of the first period in the iteration and all its successive periods before the period in which the increase occurs.
$1^{\text {st }}$ Iteration: the stating period is 1

$$
\begin{gathered}
U C(i)=\frac{C_{O}+C_{h} \times \sum_{t=1}^{i}(t-1) D_{\mathrm{t}}}{\sum_{t=1}^{i} D_{t}} \\
U C(1)=\frac{C_{O}+C_{h} \times \sum_{t=1}^{1}(t-1) D_{\mathrm{t}}}{\sum_{t=1}^{1} D_{t}}=\frac{C_{O}+0}{D_{1}}=\frac{100}{10}=10 \\
U C(2)=\frac{C_{O}+C_{h} \times D_{2}}{D_{1}+D_{2}}=\frac{100+2 \times 25}{10+25}=4.28 \\
U C(3)=\frac{C_{O}+C_{h} \times\left(1 D_{2}+2 D_{3}\right)}{D_{1}+D_{2}+D_{3}}=\frac{100+2 \times 25+2 \times 2 \times 15}{10+25+15} \\
U C(4)=\frac{C_{O}+C_{h} \times\left(1 D_{2}+2 D_{3}+3 D_{4}\right)}{D_{1}+D_{2}+D_{3}+D_{4}} \\
=\frac{100+2 \times 25+2 \times 2 \times 15+2 \times 3 \times 40}{10+25+15+40}=5
\end{gathered}
$$

The stopping criterion i.e. Ineq. 4-4 is satisfied for $i=3$ :

$$
\begin{gathered}
U C(3) \leq U C(3-1) \& \\
U C(3)<U C(3+1)
\end{gathered}
$$

Now the first order is placed such that it covers period 1,2 and 3 with quantity $10+25+15=50$.
$2^{\text {nd }}$ Iteration:Although the starting period in this iteration is 4 but we set $i$ equal to 1 for the calculation.

$$
\begin{aligned}
& U C(1)=\frac{C_{O}+0 D_{4}}{D_{4}}=\frac{100}{40}=2.5 ; \\
& U C(2)=\frac{C_{O}+C_{h} \times D_{5}}{D_{4}+D_{5}}=\frac{100+2 \times 30}{40+30}=2.2857 \\
& U C(3)=\frac{C_{O}+C_{h} \times\left(1 D_{5}+2 D_{6}\right)}{D_{4}+D_{5}+D_{6}}=\frac{100+2 \times 30+2 \times 2 \times 0}{40+30+0} \\
& \begin{array}{r}
=2.2857
\end{array} \\
& \begin{array}{r}
U C(4)=\frac{C_{O}+C_{h} \times\left(D_{5}+2 D_{6}+3 D_{7}\right)}{D_{4}+D_{5}+D_{6}+D_{7}} \\
\quad=\frac{100+2 \times 30+2 \times 2 \times 0+2 \times 3 \times 5}{40+30+0+5}=2.53
\end{array}
\end{aligned}
$$

The stopping criterion i.e. Ineq. 4-4 is satisfied for $\mathrm{i}=3$ :

$$
U C(3) \leq U C(3-1), U C(3)<U C(3+1)
$$

Then the second order is placed such that it covers 3 more periods i.e 4,5 and 6 with quantity $40+30+0=70$.
$3^{\text {rd }}$ Iteration:Although the starting period is 7 but for the calculation we set $i$ equal to 1 .
$U C(1)=\frac{C_{O}+0}{D_{7}}=\frac{100}{5}=20$
$U C(2)=\frac{C_{0}+C_{h} \times D_{8}}{D_{7}+D_{8}}=\frac{100+2 \times 10}{5+10}=8$
Then the third and final order is placed for the remaining periods 7 and 8 with size of $5+10=15$. The results are summarized in the following table:

| period $(\mathrm{t})$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| requirement $\left(\mathrm{D}_{\mathrm{t}}\right)$ | 10 | 25 | 15 | 40 | 30 | 0 | 5 | 10 |
| order $\left(\mathrm{Q}_{\mathrm{t}}\right)$ | 50 |  |  | 70 |  |  | 15 |  |
| Inventory at the end <br> of period $\left(\mathrm{I}_{\mathrm{t}}\right)$ | 40 | 15 | 0 | 30 | 0 | 0 | 10 | 0 |

Costs:
Ordering cost : $3 \times 100$
Holding cost : $\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{8} \mathrm{I}_{\mathrm{t}}=2(40+15+30+10)=2(95)=190$
$\mathrm{TVC}=3 \times 100+2 \times 95=490$

## 4-3-5 Least total Cost (LTC) method or Part Period Algorithm(PPA)

Part Period algorithm was first introduced by DeMatteis(1968) . This researcher points out that it works well for all environments especially for the cases having a limited number of periods. The algorithm tries to find a number of periods whose holding costs equals the ordering cost. The logic of this procedure is the same as that of classic EOQ model in which the inventory cost is minimized at the point where the holding cost equals the ordering cost. It is worth mentioning that when the demand is discrete the holding cost and the ordering cost do not become equal. Then the aim is to minimize their difference.

## Symbols

| $\mathrm{C}_{\mathrm{o}}$ | Cost per order |
| :--- | :--- |
| $\mathrm{C}_{\mathrm{h}}$ | Unit holding cost per period |
| $\mathrm{D}_{\mathrm{i}}$ | Requirement of $\mathrm{i}^{\text {t }}$ period |
| $\mathrm{pp}=(\mathrm{i}-1) \mathrm{D}_{\mathrm{i}}$ | Part Period(PP) related to $\mathrm{i}^{\text {th }}$ period |
| $A p p=\sum_{i=1}^{n}(i-1) D_{i}$ | Accumulated Part-Period for n periods |

## Definition of Part-Period and Accumulated Part-Period

One of the measurement units used in inventory subject is partperiod $(\mathrm{pp})^{1}$. By 1 pp it is meant that 1 unit of a product is held for 1

[^8]period. If one unit of a kind of a product is held for ten periods or 2 units are held for 5 periods or 10 units are held for 1 period we say that the part-period $(\mathrm{pp})$ value of all these 3 cases are the same and equal to 10 pp .

Suppose we place an order for the requirements of n periods to receive a lot of size $Q=D_{1}+D_{2}+\ldots+D_{n}$ at the beginning of Period 1 . From the amount Q , as much as $\mathrm{D}_{1}$ is consumed during Period 1. The pp measurement unit for this amount is $0 \times \mathrm{D}_{1}$. From the amount Q , as much as $D_{2}$ is consumed during Period 2. Noting that $D_{2}$ was held for one period before being consumed in Period 2, the pp measurement unit for this amount is $1 \times \mathrm{D}_{2}$.

From the amount Q , as much as $\mathrm{D}_{3}$ is consumed during Period 3 . Noting that $D_{3}$ was held for 2 periods before being consumed in Period 3, the pp measurement unit for this amount is $2 \times D_{3} \ldots$ the sum of these products i.e. $0 D_{1}+1 D_{2}+\ldots+(n-1) D_{n}=\sum_{i=1}^{n}(i-1) D_{i}$ is called accumulated part-period for n periods and is denoted by $A P P_{\mathrm{n}}$ : $A P P_{n}=\sum_{i=1}^{n}(i-1) D_{i}$

## Determination of order lot sizes

To determine the lot sizes or the orders for a time horizon with PPA algorithm you may require several iterations. In each iteration try to find the that number of periods $(\mathrm{n}=1,2, \ldots$.$) for which C_{h} \times$ $A P P_{n}=C_{o}$ or find that $n$ which makes $\left|C_{h} \times A P P_{n}-C_{o}\right|$ minimum. Therefore in iteration 1 when an increase happened after several consecutive decrease in $\left|C_{h} \times A P P_{n}-C_{o}\right|$, stop the iteration and place an order that cover the $n-1$ periods.

In the next Iteration take Period $\mathrm{n}+1$ as the starting period and act similar to iteration 1. Do this procedure until all periods in the horizon are covered. If in an iteration the stopping criterion is not satisfied place an order which cover the unplanned periods.

## Example 4-12

Find the order lot sizes for the time horizon given in the table below using LTC heuristic method. If the order cost is $\$ 300$ and the unit holding cost from one period to the next immediate period is $\$ 2$, calculate the costs.

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{D}_{\mathrm{t}}$ | 30 | 40 | 0 | 50 | 10 | 20 | 30 | 0 | 55 | 0 |

## Solution

| $C_{o}=300, C_{h}=2$ |  |  |  |
| :---: | :---: | :---: | :---: |
| 氷薜 | Covered periods | Quantity | $\begin{gathered} \left\|\mathrm{APP}_{\mathrm{n}}-\mathrm{C}_{\mathrm{o}}\right\|= \\ \left\|C_{h} \sum_{i=1}^{n}(i-1) D_{i}-C_{o}\right\| \end{gathered}$ |
| $1^{\text {st }}$ | 1 | 30 | $\|0-300\|=300$ |
|  | 1,2 | $70=30+40$ | $\|2(40 \times 1)-300\|=220$ |
|  | 1.2.3 | $0+70=70$ | 220 |
|  | 1.2.3.4 | $50+70=120$ | $\|2(40 \times 1+50 \times 3)-300\|=80$ |
|  | 1.2.3.4.5 | $\begin{aligned} & 10+120= \\ & 130 \end{aligned}$ | $\begin{array}{r} \mid 2(40 \times 1+50 \times 3+10 \times 4) \\ -300 \mid=160 \end{array}$ |

In Period 4 the difference $\left|A P P_{n}-C_{o}\right|$ has reached its minimum and an order is placed to cover periods 1 through 4

| 2nd | 5 | 10 | $\|0-300\|=300$ |
| :---: | :---: | :---: | :---: |
|  | 5.6 | 30 | $\|2(20 \times 1)-300\|=260$ |
|  | 5.6.7 | 60 | $\begin{gathered} \|2(20 \times 1+30 \times 2)-300\| \\ =140 \end{gathered}$ |
|  | 5.6.7.8 | 60 | 140 |
|  | 5.6.7.8.9 | 115 | $\begin{array}{r} \mid 2(20 \times 1+30 \times 2+55 \times 4) \\ -300 \mid=300 \end{array}$ |

In period 8 the difference $\left|\mathrm{APP}_{\mathrm{n}}-\mathrm{C}_{\mathrm{o}}\right|$ has reached its minimum and an order is placed to cover periods 5 through 8 and for the 3rd time for Period 9(and 10)

| $3^{\text {rd }}$ | 9 | 55 | 300 |
| :--- | :--- | :--- | :--- |

The summary of results are shown in the following Table

| Results of Example 4-12 with LTC or PPA method |  |  |  |  |  |  |  |  |  |  |
| :---: | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| $\mathrm{D}_{\mathrm{t}}$ | 30 | 40 | 0 | 50 | 10 | 20 | 30 | 0 | 55 | 0 |
| $\mathrm{Q}_{\mathrm{t}}$ | 120 | - | - | - | 60 | - | - | - | 55 | - |
| $\mathrm{I}_{\mathrm{t}}$ | 90 | 50 | 50 | 0 | 50 | 30 | 0 | 0 | 0 |  |

TVC $=3 C_{O}+3 \mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{8} \mathrm{I}_{\mathrm{t}}=3 \times 300+2(90+50+50+50+30)=1440$

## 4-3-6 Part Period Balancing(PPB) algorithm

The part period balancing algorithm determines the lot sizes by a procedure similar to LTC algorithm. It tries to balance the holding costs and ordering costs. Let

$$
\begin{align*}
A P P_{n} & =\sum_{i=1}^{n}(i-1) D_{i}  \tag{4-4}\\
E P P & =\frac{C_{o}}{C_{h}}=\frac{C_{o}}{I \times p} \tag{4-5}
\end{align*}
$$

If the $C_{h}$ of periods are not equal use their average in the denominator.

In each iteration the aim is to find the $n$ which APP and EPP equal. Practically stop the iteration when you reach the smallest $n$ which satisfy the following(Yilmaz, dated-nil)

$$
\begin{equation*}
A P P_{n} \geq E P P \tag{4-6}
\end{equation*}
$$

To determine the suitable $n$ in the first iteration, calculate $A P P_{n}=\sum_{i=1}^{n}(i-1) D_{i}$ for $\mathrm{n}=1,2, \ldots$ consecutively, When for the first time $A P P$ exceeds EPP stop and place an order for the periods up to the period for which the increase happen. Denote the last period before the increase stats by $n$.

In the second iteration take $\mathrm{n}+1$ as the starting period( $\mathrm{i}=1$ ) and act similar to iteration 1. Continue the procedure until the horizon is
completed. PPB algorithm usually gives results similar to those of PPA.
"Refinements to this algorithm have been developed. These refinement called look-ahead and look-backward can improve performance" see Tersine(1994) page 191.

## Example 4-13

Find the order lot sizes for the time horizon given in the table below using PPB heuristic method. If the order cost is $\$ 120$ and the unit holding cost from one period to the next immediate period is $\$ 2$, calculate the costs.

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{D}_{\mathrm{t}}$ | 40 | 15 | 0 | 35 | 0 | 20 | 5 | 15 | 30 |

## Solution

| Iteration 1 |  | Iteration 2 |  |  |
| :---: | :---: | :---: | :---: | :---: |
| n | $A p p_{n}=\sum_{i=1}^{n}(i-1) D_{i}$ | period | n | $A p p_{n}=\sum_{i=1}^{n}(i-1) D_{i}$ |
| 1 | $\begin{aligned} (1-1)(\mathrm{D} 1)=0 & <E P P \\ & =\frac{120}{2} \end{aligned}$ | 4 | 1 | $(1-1)(35)=0<E P P=60$ |
| 2 | $\begin{gathered} 0+(2-1)(15)=15<E P P= \\ 60 \end{gathered}$ | 5 | 2 | $0+(2-1)(0)=0<E P P$ |
| 3 | $15+(3-1)(0)=15<E P P$ | 6 | 3 | $0+(3-1)(20)=40<E P P$ |
| 4 | $15+(4-1)(35)=120>E P P$ | 7 | 4 | $40+(4-1)(5)=55<E P P$ |
|  |  | 8 | 5 | $55+(5-1)(15)=115>E P P$ |
| Since APP exceeds $\frac{C_{o}}{C_{h}}=$ EPP $=60$ a lot of size 55 is placed for the periods before period 4 |  |  |  | Since APP exceeds EPP a lot of size 60 is placed for periods 4 through 7 |

The third ordering quantity is $\mathrm{Q}_{3}=30+15$ for periods 8 and 9. The summary of calculations is given in the table below.

| period | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | sum |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| requirement | 40 | 15 |  | 35 |  | 20 | 5 | 15 | 30 | 160 |
| inventory carrying <br> period (i) | 0 | 1 |  |  |  |  |  |  |  |  |
| $p p=(i-1) D_{i}$ | 0 | 15 | 0 | 105 |  |  |  |  |  |  |
| $A_{\mathrm{n}}=\sum_{\mathrm{i}=1}^{\mathrm{n}}(\mathrm{i}-1) \mathrm{D}_{\mathrm{i}}$ | 0 | 15 | 15 | 120 |  |  |  |  |  |  |
| $i$ |  |  |  |  |  |  |  |  |  |  |
| $p p=(i-1) D_{i}$ |  |  |  | 0 | 0 | 40 | 15 | 60 |  |  |
| $A P P$ |  |  |  | 0 | 0 | 40 | 55 | 115 |  |  |
| $\mathrm{Q}_{\mathrm{t}}$ | 55 |  |  | 60 |  |  |  | 45 |  | 160 |
| It | 15 |  |  | 25 | 25 | 5 |  | 30 |  |  |

Ordering cost: $3 \times 120=360$
Holding cost:
$\mathrm{C}_{\mathrm{h}} \sum_{\substack{\mathrm{t}=1 \\ \mathrm{I} \\ \mathrm{I} \\ \mathrm{tVC}}}=2(15+0+0+25+25+5+0+30+0)=200$
End of example

## 4-3-7 Incremental Part- Period Algorithm(IPPA)

Increment Part-Period algorithm which was presented in Patterson and Forge (1985), is similar to PPB algorithm, but tries to balance incremental holding costs to ordering cost. In this algorithm, the lot size is continually increased as long as the incremental holding costs is less than or equal to the ordering cost(Tersine, 1994 ,p 193). La Forge(1982) showed through simulation technique that IPPA is preferable to $\mathrm{PPB}($ Shih\& $\mathrm{Fu}, 1995$ ). The objective in IPPA algorithm id to determine lot sizes that include an integer number of period requirements so that(Tersine 1994, page193)

$$
\begin{equation*}
\mathrm{C}_{\mathrm{h}}(\mathrm{n}-1) \mathrm{D}_{\mathrm{n}}=\mathrm{C}_{0} \quad \text { or } \quad \operatorname{IPP}_{\mathrm{n}}=(\mathrm{n}-1) \mathrm{D}_{\mathrm{n}}=\frac{\mathrm{C}_{0}}{\mathrm{C}_{\mathrm{h}}} \tag{4-7}
\end{equation*}
$$

where

| 193 | Classical topics in inventory cont |
| :---: | :--- |
| $C_{o}$ | The ordering cost |
| $\mathrm{C}_{h}=I P$ | Unit holding cost |
| $D_{n}$ | The requirement of nth period |
| $\mathrm{PP}_{\mathrm{n}}$ | Incremental part-period $=(\mathrm{n}-1) \mathrm{D}_{\mathrm{n}}$ |
| EPP | Economical Part-Period $=\frac{\mathrm{C}_{\mathrm{o}}}{\mathrm{C}_{\mathrm{h}}}$ |

This algorithm may require several iterations. In iteration 1 , calculate $\operatorname{IPP}_{n}=(n-1) D_{n}$ for $n=1,2, \ldots$ Stop whenever $\operatorname{IPP}_{n}$ exceeds EPP; record the last value of $n$ and denote the value of ( last $n-1$ ) by $n *$. Place an order for the periods 1 through $n^{*}$. Some references ignore the equality of IPPn with EPP ;however the author of this bookbelieves that the actual objective is to find an integer that satisfy the equality $C_{\mathrm{h}}(n-1) D_{n}=C_{o}$. Therefore if for a particular $n$ the equality happened, stop and set $n^{*}$ equal to this $n$. If the horizon is not ended perform another similar iteration with $\mathrm{n}^{*}+1$ as the starting period.

If in an iteration the stopping criterion is not satisfied place an order which cover the unplanned periods in the horizon.

IIPA has been extended to discount case (see Fu and Shih,1995). This method has easy understanding and has less calculations with respect to Silver-Meal and PPA methods. The following Flowchart helps to understand each iteration of the algorithm.

Fig 4-1 The algorithm for determining each lot size in IPPA assuming zero inventory for $\mathrm{i}^{\text {th }}$ period (Vera\&Laforge, 1985)

## Example 4-14

Find the order lot sizes for the time horizon given in the table below using IPPA heuristic method. If the order cost is $\$ 100$ and the fraction of unit holding cost from one period to the next immediate period is $2 \%$, and the unit price is $\$ 50$ calculate the costs.

## Solution

$$
\mathrm{EPP}=\frac{\mathrm{C}_{\mathrm{o}}}{\mathrm{C}_{\mathrm{h}}}=\frac{100}{0.02 \times 50}=100 .
$$

The calculations for IPPA method are as follows:

| Period $(\mathrm{t})$ | n | $\mathrm{D}_{\mathrm{n}}$ | IPP $_{\mathrm{n}}=(\mathrm{n}-1) \mathrm{D}_{\mathrm{n}}$ |
| :---: | :---: | :---: | :---: |
| 1 | 1 | 75 | $0 \times 75=0<100$ |
| 2 | 2 | 0 | $1 \times 0=0<100$ |
| 3 | 3 | 33 | $2 \times 33=66<100$ |
| 4 | 4 | 28 | $3 \times 28=84<100$ |
| 5 | 5 | 0 | $4 \times 0=0<100$ |
| 6 | 6 | 10 | $5 \times 10=50<100$ |

Since IPP does not exceed EPP=100 in any period only one order is enough to be placed with size $75+0+33+28+0+$ $10=146$ for all the horizon.

Costs:
Order cost $1 \times 100=100$
Holding Cost
$\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{6} \mathrm{I}_{\mathrm{t}}=$
$0.02 \times 50(71 * 1+71 * 1+38 * 1+10 * 1+10 * 1)=200$
TVC $=100+200=300$
The summary of the results are given in the table below:

| t | 1 | 2 | 3 | 4 | 5 | 6 | su |
| :---: | :---: | :---: | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 75 | 0 | 33 | 28 | 0 | 10 | 14 |
| $\mathrm{Q}_{\mathrm{t}}$ | 146 | - | - | - | - | - | 14 |
| $\mathrm{I}_{\mathrm{t}}$ | 71 | 71 | 38 | 10 | 10 | 0 | 20 |
| Accu- <br> mulated <br> variable <br> cost | $100+(146-75) \times$ <br> $(0.02 \times 50)=171$ | $171+$ <br> $(146-75-0) \times$ <br> $(.02 \times 50)=242$ | 280 | 290 | 300 | 300 |  |

End of example
Another example is given at the end of this chapter.

## 4-3-8 Silver -Meal algorithm

Edward Silver and Harlen Meal in 1973 proposed an algorithm for dynamic lot sizing. They did not want to minimize unit cost or total cost, but tried to minimize average cost per period(Yilmaz, dated-nil).

This method has less calculations compared to that of Wagner-Wittin and gives near optimal answer(Based on Winston, 1994 Page1050). In this algorithm. starting from a period, we are in search of that number of periods to place an order whose cost per period is minimum. The costs consists of the ordering cost plus the carrying costs related to the requirements of the periods being considered. Defining ${ }^{1} \mathrm{AC}(\mathrm{j})$ as
$A C(j)=\frac{\text { Ordering cost }+ \text { carrying cost }}{j}$

$$
\begin{align*}
& A C(j)=\frac{\left.C_{0}+\sum_{t=1}^{j}\left(C_{h}\right)\right)_{t} \times(t-1) D_{t}}{j} \\
& A C(j)=\frac{C_{0}+\sum_{t=2}^{j}\left(C_{h}\right) \times(t-1) D_{t}}{j} \tag{4-8-1}
\end{align*}
$$

If the $\left(\mathrm{C}_{\mathrm{h}}\right)_{\mathrm{t}}$ 's are the same and equal to $\mathrm{C}_{\mathrm{h}}$, then we have

$$
\begin{aligned}
& \mathrm{AC}(\mathrm{j})=\frac{\mathrm{C}_{\mathrm{O}}+\mathrm{C}_{\mathrm{h}} \times \sum_{\mathrm{t}=1}^{\mathrm{j}}(\mathrm{t}-1) \mathrm{D}_{\mathrm{t}}}{j} \\
& \quad=\frac{\mathrm{C}_{\mathrm{O}}+\mathrm{C}_{\mathrm{h}}\left(0 \mathrm{D}_{1}+1 \mathrm{D}_{2}+2 \mathrm{D}_{3}+. .+(\mathrm{j}-1) \mathrm{D}_{\mathrm{j}}\right)}{\mathrm{j}} \\
& \mathrm{AC}(1)=\frac{C_{0}+C_{h}(0) D_{1}}{1}=C_{0} \quad(4-8-2)
\end{aligned}
$$

where

| $A C(j)$ | Average cost per period |
| :---: | :--- |
| j | Number of periods |
| $C_{O}$ | Ordering cost |
| $\left(\mathrm{C}_{\mathrm{h}}\right)_{\mathrm{t}}$ | Unit holding cost related to period t |
| $C_{h}$ | Unit holding cost for all periods |
| $D_{t}$ | Requirement for period t |

This is an iterative method. In each iteration the aim is to find say j periods whose $A C(j)$, when starting from a particular period, is minimum.

To perform Silver =Meal algorithm, at the outset in iteration 1 set $\mathrm{j}=1$. It is assumed that all units assigned to Period $1\left(\mathrm{D}_{1}\right)$ is consumed

[^9]and none is transferred to the next period; therefore the holding cost for it is supposed to be zero and
$A C(1)=\frac{\text { ordering cost }+0}{1}$
Then increase j one by one and calculate $\mathrm{AC}(\mathrm{j})$ consecutively until for a particular $j$, as the value of $j$ is increased, $A C(j)$ exceeds $A C(j-1)$ for the first time. Denote this value of $j$ by $j_{1}$. Therefore the iteration is stopped whenever the following inequality is satisfied(Axater,2015 Chap 4):
$$
A C(j) \leq A C\left(\mathrm{j}_{1}-1\right) \quad 2 \leq j \leq \mathrm{j}_{1}
$$
$$
A C\left(\mathrm{j}_{1}+1\right)>A C\left(\mathrm{j}_{1}\right)
$$

The first lot is place to cover periods 1 through $\mathrm{j}_{1}: Q=\sum_{t=1}^{\mathrm{j}_{1}} D_{t}$
Go to next iteration 2 , set $\mathrm{j}=\mathrm{j}_{1}+1$, consecutively calculate $\mathrm{AC}(\mathrm{j})$ and perform similar iteration until the time horizon is covered.

This approach has performed extremely well in numerous test examples and is recommended for significantly variable demand pattern (Person \& Siver, 1991 page 317); however does not give optimal solution. It is worth mentioning that 2 situations where the heuristic does not perform well are (Tersine, 1994 page 187):
1.when the demand rate decreases rapidly with time over several periods,
2. where there are a large number of periods with zero demand.

## Example 4-15

Find the order lot sizes for the time horizon given in the table below using Silver-Meal heuristic method. If the order cost is $\$ 100$ and the unit holding cost from one period to the next immediate iod is \$2, Also calculate the costs.

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| :---: | ---: | :--- | :--- | :--- | ---: | ---: | ---: | ---: |
| $\mathrm{D}_{\mathrm{t}}$ | 10 | 25 | 15 | 40 | 30 | 0 | 5 | 10 |

## Solution

$\operatorname{AC}(j)=\frac{C_{0}+C_{h} \sum_{t=2}^{j}(t-1) D_{t}}{j} \quad A C(1)=C_{0}$
Iteration 1, starting period: 1
Calculation of $\mathrm{AC}(\mathrm{j})$ for $\mathrm{j}=1,2, \ldots$ :

$$
\begin{aligned}
& A C(1)=\frac{C_{O}+0}{C_{1}}=\frac{100}{1}=100 \\
& A C(2)=\frac{C_{O}+C_{h} \times D_{2}}{2}=\frac{100+2 \times 1 \times 25}{2}=75 \\
& A C(3)=\frac{C_{O}+C_{h} \times\left(D_{2}+2 D_{3}\right)}{3}=\frac{100+2 \times 25+2 \times 2 \times 15}{3}=70 \\
& A C(4)=\frac{C_{O}+C_{h} \times\left(D_{2}+2 D_{3}+3 D_{4}\right)}{4} \\
& =\frac{100+2(25+2 \times 15+3 \times 40)}{4}=112.5
\end{aligned}
$$

For the first time when $\mathrm{j}=4 \mathrm{AC}$ increased; therefore we stop and
plan an order of size $\mathrm{Q}=10+15+25=50$ for the requirements of periods 1,2 and 3 .

Iteration 2, starting period: 4
$\begin{aligned} & A C(1)=\frac{C_{O}+C_{h}(0) D_{1}}{1}=\frac{100}{1}=100 \\ & A C(2)=\frac{C_{O}+C_{h}\left(0 D_{4}+1 D_{5}\right)}{2}=\frac{100+2 \times 30}{2}=80 \\ & A C(3)=\frac{C_{O}+C_{h} \times\left(0 D_{4}+1 D_{5}+2 D_{6}\right)}{3} \\ &=\frac{100+2 \times 30+2 \times 2 \times 0}{3}=53.3 \\ & \mathrm{AC}(4)=\frac{\mathrm{C}_{0}+\mathrm{C}_{\mathrm{h}} \times\left(0 D_{4}+1 D_{5}+2 \mathrm{D}_{6}+3 \mathrm{D}_{7}\right)}{4} \\ & \quad=\frac{100+2(30+2 \times 0+3 \times 5)}{4}=47.51 \\ & \mathrm{AC}(5)=\frac{\mathrm{C}_{\mathrm{O}}+\mathrm{C}_{\mathrm{h}} \times\left(\mathrm{D}_{5}+2 \mathrm{D}_{6}+3 \mathrm{D}_{7}+4 \mathrm{D}_{8}\right)}{5} \\ & \quad=\frac{100+2(30+2 \times 0+3 \times 5+4 \times 10)}{5}=54\end{aligned}$
For the first time when $\mathrm{j}=5 \mathrm{AC}$ increased; therefore we stop and
plan the second order of size $\mathrm{Q}=40+30+0+5=75$ for the requirements of periods 4,5,6 and 7 .

## Iteration 3

No calculations is needed and the third order of size 10 is planed for the last period. The summary of results are given in the following table:

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | sum |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Dt | 10 | 25 | 15 | 40 | 30 | 0 | 5 | 10 | 135 |
| Qt | 50 | - | - | 75 | - | - | - | 10 | 135 |
| CO | 100 |  |  | 100 |  |  |  | 100 | 300 |
| It | 40 | 15 | 0 | 35 | 5 | 5 | 0 | 0 |  |
| $\mathrm{C}_{\mathrm{h}} \times \mathrm{I}_{\mathrm{t}}$ | 80 | 30 | 0 | 70 | 10 | 10 | 0 | 0 | 200 |

Costs:
Ordering cost= $100 \times 3=300$
Holding cost: $\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{8} \mathrm{I}_{\mathrm{t}}=2 \times\left(\mathrm{I}_{1}+\mathrm{I}_{2}+\mathrm{I}_{3}+\mathrm{I}_{4}+\mathrm{I}_{5}+\mathrm{I}_{6}+\mathrm{I}_{7}+\mathrm{I}_{8}\right)=$ $2 \times(40+15+0+35+5+5+0+0)=200$.
TVC=300+200=500

## 4-4 Wagner and Whitin's Exact Algorithm

Wagner and Whitin(1958) presented an algorithm which gives an exact solution for discrete-demand dynamic lot sizing problems of finite time horizon. Their solution causes no shortage. The algorithm assumes the periods of the horizon are of the same time length and the planned orders arrive at the beginning of the periods (not in the middle). The calculations of the algorithm are based on some theorems. The theorems are mentioned in some references including Winston(1994) page 1047. The algorithm minimizes the inventory costs of the problem.

It is worth mentioning that although the algorithms of Silver\& Meal and Wagner_\&Whitin cause less inventory costs compared to other dynamic lot sizing rules, but many companies which utilize MRP ${ }^{1}$ production planning technique use simple heuristic rules of POQ, PPB and LFL( extracted from Winton,1994, page 946).

[^10]
## 4-4-1 The steps of Wagner-Whitin Algorithm

This algorithm uses a dynamic programming approach. The steps of this algorithm are mentioned in many references. What follow is based on page 182 Winston (1994).

## Step 1

For all possible ordering alternatives related to the given time horizon calculate total variable cost denoted by Z as described below.

Suppose for the beginning of Period $t$, an order is planned with a size equal to the total requirements of period $t$ through say period $e$. The cost of this order is calculated from:

$$
\begin{equation*}
\mathrm{Z}_{\mathrm{te}}=\mathrm{Co}_{\mathrm{t}}+\sum_{\mathrm{i}=\mathrm{t}}^{\mathrm{e}} \mathrm{Ch}_{\mathrm{i}}\left(\mathrm{Q}_{\mathrm{te}}-\mathrm{Q}_{\mathrm{ti}}\right)+\mathrm{p}_{\mathrm{t}} \mathrm{Q}_{\mathrm{te}} \tag{4-9}
\end{equation*}
$$

Where

| $\mathrm{Z}_{\mathrm{te}}$ | total variable cost of the order planned for periods t to e |
| :---: | :--- |
| $\mathrm{Co}_{\mathrm{t}}$ | ordering cost per order |
| $\mathrm{Ch}_{\mathrm{t}}=\mathrm{IP}_{\mathrm{t}}$ | unit holding cost for period t |
| $\mathrm{P}_{\mathrm{t}}$ | unit price of period t |
| $\mathrm{Q}_{\mathrm{te}}$ | sum of requirements of Period $t$ to Period $e: \sum_{\mathrm{i}=\mathrm{t}}^{\mathrm{e}} \mathrm{D}_{\mathrm{i}}=\mathrm{Q}_{\mathrm{te}}$ |
| N | number of periods available in the time horizon |

If for $t=1,2, . ., N \quad P=P_{t}, C_{o} \quad C_{o_{t}}$ and $C_{h} \quad C_{h_{t}}$ then(Tersine, 1994 p182):
$\mathrm{Z}_{\mathrm{te}}=\mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{i}=\mathrm{t}}^{\mathrm{e}}\left(\mathrm{Q}_{\mathrm{te}}-\mathrm{Q}_{\mathrm{ti}}\right) \quad 1 \leq t \leq e \leq N \quad(4-10)$

## Step 2

Assuming the inventory at the end of Period e is zero, calculate $\mathrm{f}_{1 \times \ldots ،} \mathrm{f}_{\mathrm{N}}$ from:
$\mathrm{f}_{\mathrm{e}}=\underbrace{\operatorname{Min}}_{\text {for }}\left(\mathrm{Z}_{\mathrm{t}=1, \ldots, \mathrm{e}}+\mathrm{f}_{\mathrm{t}-1}\right) \quad \mathrm{e}=1,2, \ldots, \mathrm{~N} \quad \mathrm{f}_{0}=0$
Or
$f_{e}=\operatorname{Min}\left(Z_{1 e}+f_{0}, \quad Z_{2 e}+f_{1}, \ldots, \quad Z_{\text {ee }}+f_{e-1}\right) \quad e=1,2, \ldots, N$
Or for $e=1,2, \ldots, N$

```
\(f_{e}=\operatorname{Min}\left(f_{1 e}, f_{2 e}, \ldots, f_{e e}\right), e=1,2, \ldots, N\)
Where
    \(f_{1 e} \quad\) The cost of \(Q_{1 e}\), the order assigned to period 1 through e: \(f_{1 e}=Z_{1, e}+f_{0}, f_{0}=0\)
    \(f_{2 e} \quad\) The cost of \(Q_{2 e}\),the order assigned to period 2through e: \(f_{2 e}=Z_{2, e}+f_{1}\),
    \(\mathrm{f}_{\mathrm{e}-1, \mathrm{e}} \quad\) The cost related to the order assigned to period \(\mathrm{e}-1\) through \(\mathrm{e}: \mathrm{f}_{\mathrm{e}-1, \mathrm{e}}=\mathrm{Z}_{\mathrm{e}-1, \mathrm{e}}+\mathrm{f}_{\mathrm{e}-1}\),
    \(f_{e, e} \quad\) The cost of \(Q_{e e}\),the order assigned to period \(e: f_{e, e}=Z_{e, e}+f_{e-1}\),
```

Therefore in this step, for each period $(\mathrm{e}=1,2, \ldots, \mathrm{~N})$ all combinations of ordering alternatives as well as $\mathrm{f}_{\mathrm{e}}$ strategy are compared and the combination with lowest cost is recorded as $f_{e}$ strategy. It is proved that the value obtained for $f_{N}$ is the optimal ordering cost i.e. the cost of the optimal order schedule(Tersine, 1994 page182).

| I | $f_{N}=Z_{w, N}+f_{w-1}$ | The last order happens in Period $w$ to meet the <br> requirements of periods $w$ to $N$ |
| :--- | :--- | :--- |
| II | $f_{w-1}$ <br> $=Z_{u s w-1}+f_{u-1}$ | The order just before the last order is made in <br> Period u to meet the requirements of periods $u$ <br> to w-1 $\left(Z_{u w-1}\right)$, |
| III | $\mathrm{f}_{\mathrm{u}-1}=\mathrm{Z}_{1, \mathrm{u}-1}+\mathrm{f}_{0}$ | The 1st order is planned for Period 1 to cover <br> the requirements of periods 1 through $u-$ <br> $1\left(\mathrm{Z}_{1 \mathrm{u}-1}\right)$. |

## Step 3

To convert $f_{N}$ strategy obtained above into optimal order quantities, act by observing the orders backward .

## Example 4-16

From the data given in the following table determine the order quantities by The Wagner Whitin algorithm ;also calculate the costs assuming $\mathrm{C}_{\mathrm{h}}=\$ 1 \quad \mathrm{C}_{\mathrm{O}}=\$ 40$.

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 2 | 12 | 4 | 8 | 15 | 25 | 20 | 5 | 10 | 20 | 5 | 20 |

## Solution

Step 1 :Calculation of $Z_{t e}=C_{o}+C_{h} \sum_{i=t}^{e}\left(Q_{t e}-Q_{t i}\right)$ :
Period 1

$$
\begin{aligned}
& \mathrm{Z}_{11}=\mathrm{C}_{\mathrm{o}_{1}}+\sum_{\mathrm{i}_{1}=1}^{1} \mathrm{C}_{\mathrm{h}_{\mathrm{i}}}\left(Q_{11}-Q_{11}\right)=40+1(2-2)=40 \\
& \mathrm{Z}_{12}=\mathrm{C}_{\mathrm{o}_{1}}+\mathrm{C}_{\mathrm{h}_{1}}\left(Q_{12}-Q_{11}\right)+\mathrm{C}_{\mathrm{h}_{2}}\left(Q_{12}-Q_{12}\right) \\
& \quad=40+1(14-2)+1(14-14)=52 \\
& \mathrm{Z}_{13}=40+16+4=60, \mathrm{Z}_{14}=40+24+12+8=84, \mathrm{Z}_{15} \\
& \quad=144 \\
& \mathrm{Z}_{16}=269 \quad \mathrm{Z}_{17}=389 \\
& \mathrm{Z}_{18}=424 \quad \begin{array}{l}
\mathrm{Z}_{19}=504 \quad \\
\quad \begin{array}{l}
\text { Z }
\end{array} \\
=954
\end{array}
\end{aligned}
$$

Period 2

$$
\begin{aligned}
& \mathrm{Z}_{22}=\mathrm{C}_{\mathrm{o}_{2}}+\sum_{\mathrm{i}=2}^{2} \mathrm{C}_{\mathrm{h}_{\mathrm{i}}}\left(Q_{22}-Q_{22}\right)=40+1(12-12)=40 \\
& \mathrm{Z}_{23}=\mathrm{C}_{\mathrm{o}_{2}}+\mathrm{C}_{\mathrm{h}_{2}}\left(Q_{23}-Q_{22}\right)+\mathrm{C}_{\mathrm{h}_{2}}\left(Q_{23}-Q_{23}\right)=40+4=44 \\
& \mathrm{Z}_{24}=40+12+8=60 \quad \mathrm{Z}_{25}=40+27+23+15=105 \quad \mathrm{Z}_{26}=205 \\
& \mathrm{Z}_{27}=305 \quad \mathrm{Z}_{28}=335 \\
& \mathrm{Z}_{29}=405 \quad \mathrm{Z}_{2-10}=565 \quad \mathrm{Z}_{2-11}=610 \\
& \mathrm{Z}_{2-12}=810
\end{aligned}
$$

Period 3
$\mathrm{Z}_{33}=\mathrm{C}_{\mathrm{o}_{3}}+\mathrm{C}_{\mathrm{h}_{3}}\left(Q_{33}-Q_{33}\right)=40$
$\mathrm{Z}_{34}=\mathrm{C}_{\mathrm{o}_{3}}+\mathrm{C}_{\mathrm{h}_{3}}\left(Q_{34}-Q_{33}\right)+\mathrm{C}_{\mathrm{h}_{3}}\left(Q_{34}-Q_{34}\right)=40+8=48$
$\mathrm{Z}_{35}=40+23+15=78 \quad \mathrm{Z}_{36}=40+48+40+25=153$
$\mathrm{Z}_{37}=233$
$\mathrm{Z}_{38}=258$

$$
\begin{gathered}
\mathrm{Z}_{39}=318 \\
=678
\end{gathered}
$$

Period 4

$$
\begin{aligned}
& \mathrm{Z}_{44}=\mathrm{C}_{\mathrm{o}_{4}}+\mathrm{C}_{\mathrm{h}_{4}}\left(Q_{44}-Q_{44}\right)=40 \\
& \mathrm{Z}_{45}=\mathrm{C}_{\mathrm{o}_{4}}+\mathrm{C}_{\mathrm{h}_{4}}\left(Q_{45}-Q_{44}\right)+\mathrm{C}_{\mathrm{h}_{4}}\left(Q_{45}-Q_{45}\right)=55 \\
& \mathrm{Z}_{46}=40+40+25=105 \quad \mathrm{Z}_{47}=40+60+45+20=165 \\
& \mathrm{Z}_{48}=185
\end{aligned}
$$

$\mathrm{Z}_{49}=235 \quad \mathrm{Z}_{4-10}=355 \quad \mathrm{Z}_{4-11}=390 \quad \mathrm{Z}_{4-12}=550$
Period 5
$\mathrm{Z}_{55}=\mathrm{C}_{\mathrm{o}_{5}}+\mathrm{C}_{\mathrm{h}_{5}}\left(Q_{55}-Q_{55}\right)=40$
$\mathrm{Z}_{56}=\mathrm{C}_{\mathrm{o}_{5}}+\mathrm{C}_{\mathrm{h}_{5}}\left(Q_{56}-Q_{55}\right)+\mathrm{C}_{\mathrm{h}_{5}}\left(Q_{56}-Q_{56}\right)=40+25=65$
$\mathrm{Z}_{57}=40+45+20=105 \quad \mathrm{Z}_{58}=40+50+25+5=120$
$\mathrm{Z}_{59}=160 \quad \mathrm{Z}_{5-10}=260 \quad \mathrm{Z}_{5-11}=290 \quad \mathrm{Z}_{5-12}=430$
Period 6
$\mathrm{Z}_{66}=\mathrm{C}_{\mathrm{o}_{6}}+\mathrm{C}_{\mathrm{h}_{6}}\left(Q_{66}-Q_{66}\right)=40$
$\mathrm{Z}_{67}=\mathrm{C}_{\mathrm{o}_{6}}+\mathrm{C}_{\mathrm{h}_{6}}\left(Q_{67}-Q_{66}\right)+\mathrm{C}_{\mathrm{h}_{6}}\left(Q_{67}-Q_{67}\right)=40+20=60$
$\mathrm{Z}_{68}=40+25+5=70 \quad \mathrm{Z}_{69}=40+35+15+10=100$
$\mathrm{Z}_{6-10}=140$
$\mathrm{Z}_{6-11}=205 \quad \mathrm{Z}_{6-12}=325$
Period 7
$\mathrm{Z}_{77}=\mathrm{C}_{\mathrm{o}_{7}}+\mathrm{C}_{\mathrm{h}_{7}}\left(Q_{77}-Q_{77}\right)=40$
$\mathrm{Z}_{78}=\mathrm{C}_{\mathrm{o}_{7}}+\mathrm{C}_{\mathrm{h}_{7}}\left(Q_{78}-Q_{77}\right)+\mathrm{C}_{\mathrm{h}_{7}}\left(Q_{78}-Q_{78}\right)=40+5=45$
$\mathrm{Z}_{79}=40+15+10=65 \quad \mathrm{Z}_{7-10}=40+35+30+20$

$$
=125
$$

$\mathrm{Z}_{7-11}=145 \quad \mathrm{Z}_{7-12}=245$

## Period 8

$\mathrm{Z}_{88}=\mathrm{C}_{\mathrm{o}_{8}}+\mathrm{C}_{\mathrm{h}_{8}}\left(Q_{88}-Q_{88}\right)=40$
$\mathrm{Z}_{89}=\mathrm{C}_{\mathrm{o}_{8}}+\mathrm{C}_{\mathrm{h}_{8}}\left(Q_{89}-Q_{88}\right)+\mathrm{C}_{\mathrm{h}_{8}}\left(Q_{89}-Q_{89}\right)=40+10=50$
$\mathrm{Z}_{8-10}=40+30+20=90 \quad \mathrm{Z}_{8-11}=40+35+25+5=105$
$\mathrm{Z}_{8-12}=185$
Period 9
$\mathrm{Z}_{99}=\mathrm{C}_{\mathrm{o}_{9}}+\mathrm{C}_{\mathrm{h}_{9}}\left(Q_{99}-Q_{99}\right)=40$
$\mathrm{Z}_{9-10}=\mathrm{C}_{\mathrm{o}_{9}}+\mathrm{C}_{\mathrm{h}_{9}}\left(Q_{9-10}-Q_{99}\right)+\mathrm{C}_{\mathrm{h}_{9}}\left(Q_{9-10}-Q_{9-10}\right)=40+20$ $=60$
$\mathrm{Z}_{9-11}=40+25+5=70 \quad \mathrm{Z}_{9-12}=40+45+25+20=130$
Period 10
$\mathrm{Z}_{10-10}=\mathrm{C}_{\mathrm{o}_{10}}+\mathrm{C}_{\mathrm{h}_{10}}\left(Q_{10-10}-Q_{10-10}\right)=40$
$\mathrm{Z}_{10-11}=\mathrm{C}_{\mathrm{o}_{10}}+\mathrm{C}_{\mathrm{h}_{10}}\left(Q_{10-11}-Q_{10-10}\right)+\mathrm{C}_{\mathrm{h}_{10}}\left(Q_{10-11}-Q_{10-11}\right)$

$$
=40+5=45
$$

$\mathrm{Z}_{10-12}=40+25+20=85$
Period 11
$\mathrm{Z}_{11-11}=\mathrm{C}_{\mathrm{o}_{11}}+\mathrm{C}_{\mathrm{h}_{11}}\left(Q_{11-11}-Q_{11-11}\right)=40$

$$
\begin{aligned}
\mathrm{Z}_{11-12}=\mathrm{C}_{\mathrm{o}_{11}} & +\mathrm{C}_{\mathrm{h}_{11}}\left(Q_{11-12}-Q_{11-11}\right)+\mathrm{C}_{\mathrm{h}_{11}}\left(Q_{11-12}-Q_{11-12}\right) \\
& =40+20=60
\end{aligned}
$$

Period 12
$Z_{12-12}=40$
Step 2 Calculation of $f_{e}=\underbrace{\operatorname{Min}}_{\text {for }}\left(Z_{t e}+f_{t-1}\right)$ for $(e=$ 1, ...,12)
$\mathrm{f}_{0}=0$
$\mathrm{f}_{1}=\min \left(\mathrm{Z}_{11}+\mathrm{f}_{0}\right)=\min (40+0)=40$
$\mathrm{f}_{2}=\min \left(\mathrm{Z}_{12}+\mathrm{f}_{0}, \mathrm{Z}_{22}+\mathrm{f}_{1}\right)=\min (52+0,40+40)=52$
$\mathrm{f}_{3}=\min \left(\mathrm{Z}_{13}+\mathrm{f}_{0}, \mathrm{Z}_{23}+\mathrm{f}_{1}, \mathrm{Z}_{33}+\mathrm{f}_{2}\right)=\min (60+0,44+40,40+52)=60$ $\mathrm{f}_{4}=\min \left(\mathrm{Z}_{14}+\mathrm{f}_{0}, \mathrm{Z}_{24}+\mathrm{f}_{1}, \mathrm{Z}_{34}+\mathrm{f}_{2}, \mathrm{Z}_{44}+\mathrm{f}_{3}\right)=\min (84+$ $0,60+40,48+52,40+60)=84$
$\mathrm{f}_{5}=\min \left(\mathrm{Z}_{15}+\mathrm{f}_{0}, \mathrm{Z}_{25}+\mathrm{f}_{1}, \mathrm{Z}_{35}+\mathrm{f}_{2}, \mathrm{Z}_{45}+\mathrm{f}_{3}, \mathrm{Z}_{55}+\mathrm{f}_{4}\right)$
$=\min (144+0,105+40,78+52,55+60,40+84)=115$

$+\mathrm{f}_{9}$ )
$=\min (684+0,565+40,458+52,355+60$,

Step 3 Finding optimal combinations and converting the optimal solution $f_{N}=f_{12}=295$ into an optimal ordering plan

The optimal among the costs are

$$
\begin{aligned}
& \mathrm{f}_{\mathrm{N}}=\mathrm{Z}_{\mathrm{w}, \mathrm{~N}}+\mathrm{f}_{\mathrm{w}-1} \\
& \quad \mathrm{f}_{12}=\mathrm{Z}_{12,12}+\mathrm{f}_{11}=295
\end{aligned}
$$

The final order which occurs at Period $\mathrm{w}=12$ covers the demand of Perio2 12 with size 20

To determine the order prior to the last order :
$\mathrm{f}_{\mathrm{w}-1}=\mathrm{Z}_{\mathrm{u}, \mathrm{w}-1}+\mathrm{f}_{\mathrm{u}-1} \quad \mathrm{w}=12$
$\mathrm{f}_{12-1}=\mathrm{Z}_{\mathrm{u}, 11}+\mathrm{f}_{\mathrm{u}-1}$
$\mathrm{f}_{11}=255$ corresponds to $\mathrm{f}_{8} \& Z_{9,11}$ then $\mathrm{Z}_{\mathrm{u}, 11}+\mathrm{f}_{\mathrm{u}-1}=\mathrm{Z}_{9,11}+\mathrm{f}_{8}$ and $u=9$

The order prior to the last order is made at period $u=9$ and covers the requirements of periods 9 through $11 \mathrm{w}-1=11\left(\mathrm{Z}_{9,11}\right)$ with size $10+20+5=35$.

For the order prior to the final order we considered $f_{11}$.
the $3^{\text {rd }}$ order from the end
For the $3^{\text {rd }}$ order from the end let us consider $\mathrm{f}_{8}$
$Z_{u, w-1}+f_{u-1}=f_{8}=Z_{6,8}+f_{5}=185$

The $3^{\text {rd }}$ order from the end is made for the periods 6 through 8 with size $25+20+5=50$.

For the $4^{\text {th }}$ order from the end ,consider $f_{5}$
$Z_{u s w-1}+f_{u-1}=f_{5}=Z_{4,5}+f_{3}=175$
The $4^{\text {th }}$ order from the end is made for the periods 4 and 5 with size 23.

For the $5^{\text {th }}$ order from the end ,consider $\mathrm{f}_{3}$
$Z_{u s w-1}+f_{u-1}=f_{3}=Z_{1,3}+f_{0}=65$
The $5^{\text {th }}$ order from the end is made for the periods $1,2,3$ with size 18. This is the first order. The horizon is covered.

The orders could be determined from Z's:
$\mathrm{Z}_{1,3,}, \quad \mathrm{Z}_{4,5,5}, \mathrm{Z}_{6,8}, \quad, \mathrm{Z}_{9,11} \quad, \mathrm{Z}_{12,12}$
Therefore the algorithm give the following plan which is optimal:
The $1^{\text {st }}$ order of size 18 for periods 1 through 3
The second order of size 23 for periods $4 \& 5$
The third order of size 50 for periods 6 through 8
The $4^{\text {th }}$ order of size 35 for periods 9 through 11
The last order of size 20 for Period 12.
The results summary is mentioned in the following table:

| Wagner-Whitin Algorithm |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| Dt | 2 | 12 | 4 | 8 | 15 | 25 | 20 | 5 | 10 | 20 | 5 | 20 |
| $\mathrm{Q}_{\mathrm{t}}$ | 18 | - | - | 23 | - | 50 | - | - | 35 | - | - | 20 |
| $\mathrm{I}_{\mathrm{t}}$ | 16 | 4 | 0 | 15 | 0 | 25 | 5 | 0 | 25 | 5 | 0 | 0 |

Cost:
$\mathrm{TVC}=5 \mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{12} \mathrm{I}_{\mathrm{t}}=200+1(16+4+\cdots+5+0+0)=200+95=295$

## Example 4-17 ${ }^{1}$

Find the order lot sizes for the time horizon given in the table below using Wagner-Whitin method. If the unit price is $\$ 50$, the ordering cost is $\$ 100$ and the unit holding cost from one period to the next immediate period is $\$ 0.02$, Also calculate the costs.

| t | 1 | 2 | 3 | 4 | 5 | 6 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 75 | 0 | 33 | 28 | 0 | 10 |

## Solution

Step 1 calculations of $Z^{\prime}$ s from $Z_{t e}=C_{o}+C_{h} \sum_{i=t}^{e}\left(Q_{t e}-Q_{t i}\right)$ :
a)
calculation of $\mathrm{Z}_{1 \mathrm{e}}, \mathrm{e}=1,2, . . \mathrm{N}=6$ :
$\mathrm{C}_{\mathrm{o}}=\$ 100 \quad \mathrm{C}_{\mathrm{h}}=0.02 \times 50=1$ dollar $\quad \mathrm{Q}_{\mathrm{te}}=$ $\sum_{i=t}^{e} D_{i}$
$\mathrm{Z}_{11}=\mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{i}=1}^{\mathrm{e}=1}\left(\mathrm{Q}_{1 \mathrm{e}}-\mathrm{Q}_{1 \mathrm{i}}\right)=100+1\left(\mathrm{Q}_{11}-\mathrm{Q}_{11}\right)=100$
$\mathrm{Z}_{12}=\mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{i}=1}^{\substack{\mathrm{e}=2}}\left(\mathrm{Q}_{1 \mathrm{e}}-\mathrm{Q}_{1 \mathrm{i}}\right)=$
$100+\mathrm{C}_{\mathrm{h}}\left(\mathrm{Q}_{12}-\mathrm{Q}_{11}\right)+\mathrm{C}_{\mathrm{h}}\left(\mathrm{Q}_{12}-\mathrm{Q}_{12}\right)$

$$
\begin{aligned}
& \mathrm{Z}_{55}=\mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\substack{\mathrm{i}=5}}^{\mathrm{e}=5}\left(\mathrm{Q}_{5 \mathrm{e}}-\mathrm{Q}_{5 \mathrm{i}}\right)=100 \\
& \mathrm{Z}_{56}=\mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{i}=5}^{\mathrm{e}=6} \boldsymbol{j}\left(\mathrm{Q}_{5 \mathrm{e}}-\mathrm{Q}_{5 \mathrm{i}}\right)= \\
& \begin{array}{r}
100+1\left(\mathrm{Q}_{56}-\mathrm{Q}_{55}\right)+1\left(\mathrm{Q}_{56}-\mathrm{Q}_{56}\right) \\
\\
=100+100+1(10-0)+1(10-10)=110
\end{array}
\end{aligned}
$$

## f)calculation of $Z_{66}$

$Z_{66}=C_{o}+C_{h} \sum_{i=6}^{e=6}\left(Q_{6 e}-Q_{6 i}\right)=100+1\left(Q_{66}-Q_{66}\right)=100$
The following table shows the result of calculating $\mathrm{Z}_{\mathrm{te}}$ 's:

| values oftotal variable costs: $Z_{\text {te }}, 1 \leq t \leq e \leq N$ |  |  |  |  |  |  |  | (Tersine,1994 page 183) |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| t | e | 1 | 2 | 3 | 4 | 5 |  |  |  |  |
| t |  |  |  |  |  | 6 |  |  |  |  |
| 1 | 10 | 100 | 166 | 25 | 250 | 300 |  |  |  |  |
| 2 |  | 100 | 133 | 18 | 189 | 229 |  |  |  |  |
| 3 |  |  | 100 | 12 | 128 | 158 |  |  |  |  |
| 4 |  |  |  | 10 | 100 | 120 |  |  |  |  |
| 5 |  |  |  |  | 100 | 110 |  |  |  |  |
| 6 |  |  |  |  |  | 100 |  |  |  |  |

## Step 2

calculation of minimum of possible cost in periods 1 through $e\left(f_{e}\right)$ :
To obtain the minimum of possible cost in periods 1 through e we need to calculate for $\mathrm{e}=1, \ldots, \mathrm{~N}=6$ the following value:
$f_{e}=\underbrace{M i n}_{\text {for }} \underbrace{}_{t=1, \ldots, e}\left(Z_{t e}+f_{t-1}\right)$ or
$f_{e}=\operatorname{Min}\left(Z_{1 e}+f_{0}, \quad Z_{2 e}+f_{1}, \ldots, \quad, Z_{e e}+f_{e-1}\right) \quad e=$ $1, \ldots, N$
$f_{e}=\operatorname{Min}\left(Z_{t e}+f_{t-1} \quad\right.$ for $t=1, \ldots, 6 \quad f_{0}=0$

$$
\begin{aligned}
f_{1} & =\operatorname{Min}\left(Z_{11}+f_{0}\right)=(100+0) \\
& =100 \quad \text { for } Z_{11}+f_{0}, \\
f_{2} & =\operatorname{Min}\left(Z_{12}+f_{0}, Z_{22}+f_{1}\right)=\operatorname{Min}(100+0,100+100) \\
& =100 \text { for } Z_{12}+f_{0}, \\
f_{3} & =\operatorname{Min}\left(Z_{13}+f_{0}, Z_{23}+f_{1}, Z_{33}+f_{2}\right)=(166+0,133+100,100+100) \\
& =166 \quad \text { for } Z_{13}+f_{0}, \\
f_{4} & =\operatorname{Min}\left(Z_{14}+f_{0}, Z_{24}+f_{1}, Z_{34}+f_{2}, Z_{44}+f_{3}\right) \\
& =(250+0,189+100,128+100,100+166) \\
& =228 \quad \text { for } Z_{34}+f_{2}, \\
f_{5} & =\operatorname{Min}\left(Z_{15}+f_{0}, Z_{25}+f_{1}, Z_{35}+f_{2}, Z_{45}+f_{3}, Z_{55}+f_{4}\right) \\
& =(250+0,189+100,128+100,100+166,100+228) \\
& =228 \quad \text { for } Z_{35}+f_{2}, \\
f_{6} & =\operatorname{Min}\left(Z_{16}+f_{0}, Z_{26}+f_{1}, Z_{36}+f_{2}, Z_{46}+f_{3}, Z_{56}+f_{4}, Z_{66}+f_{5}\right) \\
& =(300+0,229+100,158+100,120+166,110+228,100+228) \\
& =258 \quad \text { for } Z_{36}+f_{2} .
\end{aligned}
$$

The table below shows the alternatives of variable $\operatorname{costs}\left(\mathrm{Z}_{\mathrm{te}}+\mathrm{f}_{\mathrm{t}-1}\right.$ and $f_{e}$ values:

| Values of variable costs $\left(\mathrm{Z}_{\mathrm{te}}+\mathrm{f}_{\mathrm{t}-1}\right)$ and $\mathrm{f}_{\mathrm{e}}$ |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| t | e | 1 | 2 | 3 | 4 | 5 |
| t |  |  |  | 6 |  |  |
|  | 1 | 10 | 10 | 166 | 250 | 250 |
| 2 |  | 20 | 233 | 289 | 289 | 300 |
| 3 |  |  | 200 | 228 | 228 | 258 |
| 4 |  |  |  | 266 | 266 | 286 |
| 5 |  |  |  |  | 328 | 338 |
| 6 |  |  |  |  |  | 328 |
| $\mathrm{f}_{\mathrm{e}}$ | 10 | 10 | 166 | 228 | 228 | 258 |

Step 3 Finding optimal combinations and converting the optimal solution $f_{N}$ into an optimal ordering plan

Determine the last order by applying Criterion I of step 3 mentioned in the algorithm :

In this example $f_{6}=f_{N}$ corresponds to the combination of " $f_{2}$ and $Z_{36}$ i.e. according to Criterion I
$\mathrm{f}_{\mathrm{N}}=\mathrm{Z}_{\mathrm{w}, \mathrm{N}}+\mathrm{f}_{\mathrm{w}-1}=\mathrm{Z}_{36}+\mathrm{f}_{2}$

According to this criterion the final order is planned for Period $\mathrm{w}=3$ for the requirement of periods 3 through 6 with lot size of $33+28+0+10=71$

Determining the order prior to last order by applying Criterion II of step 3 mentioned in the algorithm :
$f_{w-1}=Z_{u, w-1}+f_{u-1} \quad w=3$ $\mathrm{f}_{\mathrm{w}-1}=\mathrm{Z}_{\mathrm{u}, \mathrm{w}-1}+\mathrm{f}_{\mathrm{u}-1} \quad \mathrm{w}=3 \quad \mathrm{f}_{2}=\mathrm{Z}_{\mathrm{u}, 2}+\mathrm{f}_{\mathrm{u}-1}$
$f_{2}$ was obtained from the combination of $f_{0}$ and $Z_{12}$ therefore $\mathrm{u}=1$. The order is placed at Period 1. This order covers demands in periods u through w-1 i.e. periods 1 and 2 with size $75+0=75$.
These 2 orders suffice to cover the time horizon. The algorithm ends.
Therefore the method gives the following results

| t | 1 | 2 | 3 | 4 | 5 | 6 | sum |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 75 | 0 | 33 | 28 | 0 | 10 | 146 |
| $\mathrm{Q}_{\mathrm{t}}$ | 75 | - | 71 | - | - | - | 146 |
|  |  |  |  |  |  |  |  |

Costs:
Ordering cost $=2 \times 100=10$
Holding cost:
$\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{6} \mathrm{I}_{\mathrm{t}}=1(0 * 1+0 * 1+38 * 1+10 * 1+10 * 1)=58$
$\mathrm{TVC}=200+58=258$

## Example 4-18 ${ }^{1}$

Using the data given in the following table, Find the solution to this dynamic lot sizing problem by several methods and compare their costs if
$C_{h}$ per period $=\$ 1 \quad$ The setup or order cost $=C_{O}=\$ 40$

| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 2 | 12 | 4 | 8 | 15 | 25 | 20 | 5 | 10 | 20 | 5 | 20 |

[^11]
## Solution

## (i)Silver-Meal

## Iteration 1

Starting period:1

$$
\begin{aligned}
\mathrm{AC}(\mathrm{j}) & =\frac{\mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \times \sum_{t=2}^{j}(\mathrm{t}-1) \mathrm{D}_{\mathrm{t}}}{j} \\
\mathrm{AC}(1) & =40 \\
\mathrm{AC}(2) & =(40+12) / 2=26 \\
\mathrm{AC}(3) & =[40+12+(2)(4)] / 3=20 \\
\mathrm{AC}(4) & =[40+12+(2)(4)+(3)(8)] / 4=21 \quad \text { Stop }
\end{aligned}
$$

## Iteration 2

Starting period:4
$\mathrm{AC}(1)=40$
$\mathrm{AC}(2)=(40+15) / 2=27.5$
$\mathrm{AC}(3)=[40+15+(2)(25)] / 3=35 \quad$ stop

## Iteration 3

Starting period:6
$\mathrm{AC}(1)=40$
$\mathrm{AC}(2)=(40+20) / 2=30$
$\mathrm{AC}(3)=[40+20+(2)(5)] / 3=23.3333$
$\mathrm{AC}(4)=[40+20+(2)(5)+(3)(10)] / 4=25$ stop

## Iteration 4

Starting period:9
AC (1) $=40$
$\mathrm{AC}(2)=\frac{40+20}{2}=30$
$\mathrm{AC}(3)=\frac{[40+20+(2)(5)]}{3}=23.3333$
$\mathrm{AC}(4)=\frac{[40+20+(2)(5)+(3)(20)]}{4}=32.50$
stop.
Then according to Silver Meal method 5 orders have to be placed with sizes $(2+12+4) \cdot(8+15)) \cdot(25+205) \cdot(10+20+5$ and $(20)$ for Periods 1,4,6\&9
$=(2,12,4,|8,15,|25,20,5,|10,20,5| 20)$,

| Cost: |  | $\mathrm{C}_{\mathrm{h}}=1$ |  |  | $\mathrm{C}_{\mathrm{O}}=40$ |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| $\mathrm{D}_{\mathrm{t}}$ | 2 | 12 | 4 | 8 | 15 | 25 | 20 | 5 | 10 | 20 | 5 | 20 |
| $\mathrm{Q}_{\mathrm{t}}$ | 18 | - | - | 23 | - | 50 | - | - | 35 | - | - | 20 |

| t | 16 | 4 | 0 | 15 | 0 | 25 | 5 | 0 | 25 | 5 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

$\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{12} \mathrm{I}_{\mathrm{t}}=1(16+4+15+25+5+25+5)=95$
$\mathrm{TVC}=5 \mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{12} \mathrm{I}_{\mathrm{t}}=(5)(40)+95=295$.
ii)LUC

## Iteration 1

Starting period:1
$\mathrm{UC}(1)=40 / 2=20$
$\mathrm{UC}(2)=(40+12) /(2+12)=3.71$
$\mathrm{UC}(3)=(40+12+8) /(2+12+4)=3.33$
$\mathrm{UC}(4)=(40+12+8+24) /(2+12+4+8)=3.23$
$\mathrm{UC}(5)=(40+12+8+24+60) /(2+12+4+8+15)=3.51$

## Stop.

## Iteration 2

Starting period :5
UC (1) $=40 / 15=2.67$
$\mathrm{UC}(2)=(40+25) /(15+25)=1.625$
$\mathrm{UC}(3)=(40+25+40) /(15+25+20)=1.75 \quad$ Stop

## Iteration 3

Starting period:7
$\mathrm{UC}(1)=40 / 20=2$
$\mathrm{UC}(2)=(40+5) /(20+5)=1.8$
$\mathrm{UC}(3)=(40+5+20) /(20+5+10)=1.86 \quad$ stop

## Iteration 4

Starting period :9
$\mathrm{UC}(1)=40 / 10=4$
$\mathrm{UC}(2)=(40+20) /(10+20)=2$
$\mathrm{UC}(3)=(40+20+10) /(10+20+5)=2$
$\mathrm{UC}(4)=(40+20+10+60) /(10+20+5+20)=2.3636$
Solution of LUC:
$=(2,12,4,8,|15,25,|20,5,|10,20,5| 20)$,
$\mathrm{C}_{\mathrm{h}}=1 \quad \mathrm{C}_{\mathrm{O}}=40$

Cost

$$
C_{h} \sum_{t=1}^{12} I_{t}=1(24+12+\cdots+5)=104
$$

$\mathrm{TVC}=5 \mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{12} \mathrm{I}_{\mathrm{t}}=5 * 40+104=304$
iii) LTC or PPA method

This approach sets the order horizon equal to the number of periods that most closely matches the total carrying cost with the order cost, which is $\$ 40$ in this problem. Therefore, the absolute value of the difference between the holding and order costs is calculated in each period and the one with the lowest value is found.

## Iteration1

Starting period:1
Through holding cost
Period $n$

1
2
3
4

$$
\begin{array}{lccc} 
& A P P_{n}=\sum_{i=1}^{n}(i-1) D_{i} & C_{h} A P P_{n} & \left|C_{h} A P P_{n}-C_{o}\right| \\
1 & 0 & 0 & 40 \\
2 & 1 \times 12 & 12 & 28 \\
3 & 1 \times 12+2 \times 4 & 20 & 20 \\
4 & 20+3 \times 8 & 44 & 4 \leftarrow(\text { closest }) \\
5 & 44+4 \times 15 & 104 & 64
\end{array}
$$

Iteration2
Starting period:2
Through holding cost
Period $n$

| $\underline{\mathrm{n}}$ | $A P P_{n}=\sum_{i=1}^{n}(i-1) D_{i-}$ | $\left\|C_{h} A P P_{n}-C_{o}\right\|$ |
| :---: | :---: | :---: |
| 5 | 40 | 0 |
| 6 | 25 | $15 \leftarrow \mathrm{closest}$ |
| 7 | 65 | 25 |

Iteration 3: starting period:7
$\begin{array}{lcc}\underline{\mathrm{n}} & A P P_{n}=\sum_{i=1}^{n}(i-1) D_{i-} & \left|C_{h} A P P_{n}-C_{o}\right| \\ 7 & 40 & 0 \\ 8 & 5 & 35 \\ 9 & 25 & 15 \leftarrow \text { closest }\end{array}$

## $10 \quad 85$

Iteration 4: starting period:10

| $\underline{\mathrm{n}}$ | $A P P_{n}=\sum_{i=1}^{n}(i-1) D_{i-}$ | $\left\|C_{h} A P P_{n}-C_{o}\right\|$ |
| :--- | :---: | :---: |
| 10 | 40 | 0 |
| 11 | 5 | 35 |
| 12 | 45 | $5<$ closest |

Solution of LUC: $=(2,12,4,8,|15,25,|20,5,10| 20,5,20)$,
i.e.
$1^{\text {st }}$ order occurs in Period 1 with size $2+12+4+8=26$
$2^{\text {nd }}$ order occurs in Period 5 with size $25+15=40$,
$3^{\text {rd }}$ order occurs in Period 7with size 35,
Final order occurs in Period 10 with size $20+5+20=45$
The calculations are given below:

Calculations of PPA=LTC algorithm applied to Example 4-18

| Iteration | Included <br> Periods | Demand | $\mid$ holding cost - ordering cost $\mid$ |
| :---: | :---: | :---: | :---: |
| 1 | 1 | 2 | $\|0-40\|=40$ |
|  | 1.2 | 14 | $\|12-40\|=28$ |
|  | 1.2 .3 | 18 | $\|20-40\|=20$ |
|  | 1.2 .3. | 26 | $\|44-40\|=4$ |

| $\mathrm{D}_{\mathrm{t}}$ | 2 | 12 | 4 | 8 | 15 | 25 | 20 | 5 | 10 | 20 | 5 | 20 |
| $\mathrm{Q}_{\mathrm{t}}$ | 18 | - | - | 48 | - | - | 35 | - | - | 45 | - | - |
| t | 16 | 4 | 0 | 40 | 25 | 0 | 15 | 10 | 0 | 25 | 20 | 0 |

$T V C=4 \mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{12} \mathrm{I}_{\mathrm{t}}=4 *\left(C_{0}\right)+$
$C_{h} *(16+4+40+25+15+10+25+20)=160+155=315$
v) PPB Algorithm :

| Calculation of PPB algorithm applied to Example 4-18 |  |  |  |
| :---: | :---: | :---: | :---: |
| Iteration | Included <br> Periods |  | $A p p_{n}=\sum_{i=1}^{n}(i-1) D_{i}$ |
| 1 | 1 |  | 0 |
|  | 1.2 |  | $0+12$ |
|  | 1.2 .3 |  | $12+8$ |
|  | 1.2 .3 .4 |  | $20+24=44$ |

Since APP4 exceedsEPP $=\frac{40}{1}$ an order of size $\mathrm{Q}=8+15=23$ is placed for the 3 previous periods i.e.1,2\&3

| 2 | 4 |  | 0 |
| :---: | :--- | :--- | :---: |
|  | 4.5 |  | $0+15=15$ |
|  | 4.5 .6 |  | $15+50=65$ |

Since APP6 exceedsEPP $=\frac{40}{1}$ an order is placed for Periods $4 \& 5$ of size $Q=8+15=23$

| 3 | 6 |  | 0 |
| :--- | :--- | :--- | :---: | :---: |
|  | 6.7 |  | $0+20=20$ |
|  | 6.7 .8 |  | $20+10=30$ |
|  | $6.7 .8,9$ |  | $30+30=60$ |
| Since APP9 |  | exceeds EPP $=\frac{40}{1} \quad$ an order of size |  | $\mathrm{Q}=5+20+25=50$ is placed for the 3 previous periods i.e.6,7\&8

| 4 | 9 |  | 0 |
| :--- | :--- | :--- | :---: |
|  | 9.10 |  | 20 |
|  | 9.10 .11 |  | $20+2(5)=30$ |
|  | 9.10 .11 |  | $30+60=90$ |

Since APP12 exceedsEPP $=\frac{40}{1}$ an order of size $\mathrm{Q}=10+20+5=35$ is placed for the 3 previous periods i.e. $9,10 \& 11$.
Furthermore an order is placed for Period 12 with size 20 the final order.

| The summary of PPB algorithm |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| t | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| $\mathrm{D}_{\mathrm{t}}$ | 2 | 12 | 4 | 8 | 15 | 25 | 20 | 5 | 10 | 20 | 5 | 20 |
| $\mathrm{Q}_{\mathrm{t}}$ | 18 | - | - | 23 | - | 50 | - | - | 35 |  | - | 20 |
| t | 16 | 4 | 0 | 15 | 0 | 25 | 5 | 0 | 25 | 5 | 0 | 0 |

Cost
$C_{h}=1 \quad \mathrm{C}_{\mathrm{o}}=40$
TVC $=$
$5 \mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{12} \mathrm{I}_{\mathrm{t}}=200+1(16+4+\cdots+5+0+$
$0)=200+95=295$.
$\mathrm{TVC}=5 \mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{12} \mathrm{I}_{\mathrm{t}}=200+1(16+4+\cdots+5+0+0)=200+95=295$
vi )POS Method

Assume the inventory before the horizon begins is 4 units, $\mathrm{T}_{\mathrm{L}}=2$ months, POS=5, safety stock $=3$

| Results of POS |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Period(t) | -2 | -1 | 1 <br> Jan | 2 <br> Feb | 3 <br> Mar | 4 <br> Apr | 5 <br> May |
| Net Requirement( $\left.\mathrm{D}_{\mathrm{t}}\right)$ |  |  | 2 | 12 | 4 | 8 | 15 |
| Available inventory <br> $(\mathrm{It})$ |  | 4 | 42 | 30 | 26 | 18 | 3 |
| Received order <br> Planned order | 4 <br> 0 |  |  | $40=$ <br> $41-4+3$ |  |  |  |

| Results of POS(continued) |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| t | $\begin{aligned} & 6 \\ & \text { June } \end{aligned}$ | $\begin{aligned} & \hline 7 \\ & \text { July } \end{aligned}$ | $\begin{aligned} & 8 \\ & \text { Aug } \end{aligned}$ | $\begin{aligned} & 9 \\ & \text { Sep } \end{aligned}$ | $\begin{aligned} & 10 \\ & \text { Oct } \end{aligned}$ | $\begin{aligned} & 11 \\ & \text { Nov } \end{aligned}$ | $\begin{aligned} & 12 \\ & \text { Dec } \end{aligned}$ | sum |
| Net <br> Requirement(Dt) |  | 20 |  | 40 | 2010 | \% | \% | 146 |
| Available Inventory $\left(\mathrm{I}_{\mathrm{t}}\right)$ <br> Received Order |  |  | 33 | 23 | 3 | $23$ | 3 | 146 |
| Scheduled order |  |  |  | 25 |  |  |  |  |

Note That since POS $=5$, the lot size is derived from the summation the requirement of 5 consecutive periods

$$
C_{0}=40, \quad C_{h}=1,, T V C=3 \mathrm{C}_{\mathrm{o}}+\mathrm{C}_{\mathrm{h}} \sum_{\mathrm{t}=1}^{8} \mathrm{I}_{\mathrm{t}}=120+300=420
$$

## Vii ) Incremental part Period Algorithm(IPPA)

The calculations are given in the following table.
The sign * in the table means that the iteration has not arrived at the stop point i.e to the period for which $\operatorname{IPP}_{\mathrm{n}} \nsubseteq E P P$

$$
\text { where } E P P=\frac{C_{o}}{C_{h}}=\frac{40}{1} \text { and } I P P_{n}=(n-1) D_{n}
$$

Calculations of Example $4-18$ by IPPA

$T V C=5 * C_{0}+\mathrm{C}_{\mathrm{h}}(16+,,,+5)=200+95=295$
The costs of the solution of the algorithms applied to Example 4-18 are inserted in the following Table for comparison

| TVC of Algorithms' solution for Example 4-18 |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Method | Silver <br> Meal | LUC | PPA= <br> LTC | POQ= <br> EOI | PPB | Wagner <br> whitin | IPPA | Lingo |
| TVC | 295 | 304 | 299 | 315 | 295 | 295 | 329 | 295 |

## Exercises

1-What is meant by dynamic lot sizing?
2-Compare POQ and EOQ methods.
3-What is the difference between PPA and IPPA methods.
4-The requirements for the next 6 months are as follows:

| t | 1 | 2 | 3 | 4 | 5 | 6 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 0 | 10 | 30 | 40 | 60 | 20 |

The holding cost per unit product for each period is $\$ 5$. The ordering cost for the first period is $\$ 70$ and for the other periods is $\$ 200$. The lead time is one month. Use the LUC method and another approach to find the order lot sizes. Which method is better? Why?

5-( Tersine, 1994p199) An item has a unit purchase price of $\$ 45$,an ordering cost of $\$ 110$ and the carrying cost fraction per period is $2.5 \%$. Determine the order sizesusing PPB, IPPA and Silver-Meal algorithms. Which method is better? Why?

| period | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{D}_{\mathrm{t}}$ | 10 | 3 | 30 | 100 | 7 | 0 | 80 | 50 | 0 | 90 |

6-The requirements of a 12-period time horizon are given in the
following table. The holding cost fraction is $2 \%$. The ordering cost per period is $\$ 200$. Determine the order sizes using LTC, LUC \& Silver-Meal algorithms. Also solve this problem by Lingo software. Which method is better? Why?

| $t$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{D}_{\mathrm{t}}$ | 10 | 0 | 0 | 120 | 70 | 180 | 250 | 270 | 0 | 40 | 0 | 10 |

Solve example $4-1$ with Lingo, assuming that 8 units is necessary after the last period

\section*{Chapter 5}

\section*{Inventory Control under Uncertainty}

\begin{abstract}
Aims of the chapter
This chapter deals addresses the problem of inventory control under uncertainty which is an important issue in supply chain management across industrial and commercial firms. In this regard such inventory models as single period inventory, \((\mathrm{R}, \mathrm{T})\) and \((\mathrm{r}, \mathrm{Q})\) are introduced. The end of chapter deal with the application of decision making in complete uncertainty in inventory control.
\end{abstract}

\subsection*{5.1 Introduction}

As mentioned in chapter 1, the uncertainty condition could be divided into complete uncertainty conditions and risk conditions. The so-called completer uncertainty condition in inventory planning will be dealt at the end of this chapter. In risk conditions there is some records of past data which enable us to calculate the occurrence probability of the occurrence of the inventory model parameters. In what follows you will find inventory models such as single period inventory, \(\mathrm{FOI}=(\mathrm{R}, \mathrm{T})\) and FOS \(=(r, Q)\) models under risk conditions.

\subsection*{5.2 Single Period Inventory Model with Probabilistic demand}

The single period inventory model described here are used in situations where a kind of raw material or a finished product is
ordered based on the probabilistic demand for it. The demand is a random variable where occurs in only a single period. The objective of the problem is to find that level of inventory before the start of the \(\operatorname{period}(\mathrm{R})\) which maximizes profit. This model which is often called the newsboy problem or Christ- mas tree problem is used for perishable or seasonal items that could be ordered once or have a short period of consumption such as bread, flower, fruit, vegetable, newspaper, new year cards, deteriorating items, the items that are produced once and cannot be carried in inventory and sold in future periods.

\section*{In this model}
-The demand is a random variable,
-The period of consumption is relatively short, and one order for purchase or production is placed to be received at the beginning of the period.
-The salvage price is very low compared to the initial price.
- The objective in this problem is to determine an optimal level for the maximum inventory which maximizes profit.

\section*{Symbols}

A The position of inventory before placing an order
\(\mathrm{X}=\mathrm{D} \quad\) Demand
\(f(x)=\) The probability density function of variable \(f_{D}(x)\) demand
\(\mathrm{F}(\mathrm{x})=\quad \operatorname{Pr}(\mathrm{X} \leq \mathrm{x})\)
\(\mathrm{G}_{\mathrm{U}}(\mathrm{k})\) Unit loss normal integral
\(\mathrm{H} \quad\) The actual holding cost of one item not sold
\(=H^{\prime} \quad\) during the period
- L

H' The cost of disposal of one unit at the end of period
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 228 \\
\hline
\end{tabular}
\(\mathrm{K}(\mathrm{R}) \quad P(R-I)+H R+(V+\pi+H) \int_{R}^{\infty}(x-R) f(x) d x\)
\(\mathrm{L} \quad\) Salvage or sale value of one unit
\(p \quad\) Service level \((\operatorname{Pr}(\mathrm{X} \leq \mathrm{R})\)
\(P \quad\) Unit price or unit cost of production
\(P_{D}(x)\) The probability function for discrete demand
\(\mathrm{R} \quad\) The level of inventory after receiving the order
R* Optimal R
\(\mathrm{U} \quad\) The sales revenue during the period
\(\mathrm{V} \quad\) The value earned per unit sold
\(\mathrm{Y} \quad\) The cost during the period(purchase/production ,holding \&shotage)
\(\mathrm{Z} \quad\) The profit during the period
\(\pi \quad\) Unit shortage cost(lost profit not included)

Note that:

It is assumed the cost of holding for the units sold during the period is ignorable.

H , the actual holding cost for each unsold unit at the end of the period, is equal to the differencebetween the disposal \(\operatorname{cost}\left(\mathrm{H}^{\prime}\right)\) and the salvage or sale price(L) i.e.
\[
\begin{equation*}
\mathrm{H}=\mathrm{H}^{\prime}-\mathrm{L} \tag{5-1}
\end{equation*}
\]

H' and L could be zero or positive; therefore \(H\) could be negative, zero or positive.

Let the shortage cost of one unit be denoted by \(\pi\). In this model there is no time-depended shortage cost because there is only one period. By the way if in the case of shortage it is said that there is only lost profit per each shortage unit during the period then let \(\pi=0\).

As mentioned before in this model we would like to determine the inventory level after receiving the order ( R ) in such a way the the profit is maximized. For the period let

Y denotes the purchase, holding and shortage cost

U denotes sales revenue
\(\mathrm{Z}=\) the profit during the period or \(Z=U-Y \Rightarrow\)
\(E(Z)=E(U)-E(Y)\).
It is obvious if the demand is more than R the sales amount is R :
Sales volume random variable \(== \begin{cases}x & D<R \\ R & D \geq R\end{cases}\)
To deal with the model two cases are distinguished
a)The order cost or setup cost \(\left(C_{o}\right)\) is ignorable,
b) \(C_{0}\) is considerable .

\subsection*{5.2.1 Single Period Inventory Model -order/setup cost ignorable}

Let us denote the revenue per unit sold be V then the average revenue \(=V \times\) average sales volume

\subsection*{5.2.1.1 Single Period Inventory Model : \(C_{o} \cong 0 \&\) continuous demand}

If the order / setup cost \(\left(\mathrm{C}_{\mathrm{O}}\right)\) is ignorable and the demand is a continuous random variable with probability density function \(\mathbf{f}(\mathbf{x})\) then:

Average sale volume=
\[
=\int_{0}^{\infty}(\text { sale volume }) f(x) d x=\int_{0}^{R} x f(x) d x+\int_{R}^{\infty} R f(x) d x \Rightarrow
\]

Average sales volume \(=\int_{0}^{\infty} x f(x) d x-\int_{R}^{\infty} x f(x) d x+\) \(\int_{R}^{\infty} R f(x) d x=E(D)+\int_{R}^{\infty}(R-x) f(x) d x\)

Average sales revenue \(=\mathrm{E}(\mathrm{U})=V E(D)+V \int_{R}^{\infty}(R-x) f(x) d x \quad\) or
Average sales revenue \(=\mathrm{E}(\mathrm{U})=V E(D)-V \int_{R}^{\infty}(x-R) f(x) d x(5-3)\)
The total cost \(Y\) was defined as:
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 230 \\
\hline
\end{tabular}
\(\mathrm{Y}=\) purchase/production cost +holding cost+ shortage cost.
The unsold units at the end of the single period is a function of the demand :
\[
\begin{equation*}
\text { unsold units }=g(x) \tag{5-4}
\end{equation*}
\]

If the actual holding cost per unsold unit is H , then:
The average holding cost=
\(H \int_{0}^{\infty} g(x) f(x) d x=H\left[\int_{0}^{R}(R-x) f(x) d x+\int_{R}^{\infty} 0 f(x) d x\right] \Rightarrow\)
The average holding cost of the period \(=H \int_{0}^{R}(R-x) f(x) d x\).
Let the shortage which is a function of the demand be denoted by \(b(x)\) :
\[
b(x)= \begin{cases}0 & D<R  \tag{5-5}\\ x-R & D>R\end{cases}
\]

For continuous demand, the average shortage volume for the period denoted by \(\bar{b}(R)\) is equal to :
\[
\bar{b}(R)=\int_{0}^{\infty} b(x) f(x) d x=\int_{0}^{R} 0 f(x) d x+\int_{R}^{\infty}(x-R) f(x) d x
\]

This relationship after simplification is inserted in the following table as well as a similar relationship for the discrete demand.

Demand Average shortage volume for the period
continuous

Discrete
\[
\begin{align*}
& \overline{\mathrm{b}}(\mathrm{R})=\int_{\mathrm{R}^{\infty}}^{\infty}(\mathrm{x}-\mathrm{R}) \mathrm{f}(\mathrm{x}) \mathrm{dx}  \tag{5-6}\\
& \overline{\mathrm{~b}}(\mathrm{R})=\sum_{\mathrm{x}=\mathrm{R}+1}(\mathrm{x}-\mathrm{R}) \mathrm{P}_{\mathrm{D}}(\mathrm{x}) \tag{5-7}
\end{align*}
\]

Where \(f(x)\) is the probability density function for continuous demand and \(P_{D}(x)\) is the probability function for discrete demand.

If the cost per unit shortage is \(\pi\) then:
Average shortage cost for the period \(=\pi \bar{b}(R)=\pi \int_{R}^{\infty}(x-R) f(x) d x\).
Let the position of inventory before placing an order be A. If the unit price is P then

Production /purchase cost \(=P(R-A)\)
Average total cost \(=\mathrm{E}(\mathrm{Y})=\mathrm{P}(\mathrm{R}-\mathrm{A})+\mathrm{H} \int_{0}^{\mathrm{R}}(\mathrm{R}-\mathrm{x}) \mathrm{f}(\mathrm{x}) \mathrm{dx}+\)
\(\pi \int_{R}^{\infty}(x-R) f(x) d x \Rightarrow\)
\[
\begin{aligned}
& E(Y)=P(R-A)+H \int_{0}^{\infty}(R-x) f(x) d x \\
&-H \int_{R}^{\infty}(R-x) f(x) d x+\pi \int_{R}^{\infty}(x-R) f(x) d x \\
& \Longrightarrow
\end{aligned}
\]
\[
E(Y)=P(R-\mathrm{A})+H R \int_{0}^{\infty} f(x) d x-H \int_{0}^{\infty} x f(x) d x
\]
\[
-H \int_{R}^{\infty} R f(x) d x+H \int_{R}^{\infty} x f(x) d x
\]
\[
+\pi \int_{R}^{\infty} x f(x) d x-\pi R \int_{R}^{\infty} f(x) d x \Longrightarrow
\]
\[
E(Y)=P(R-\mathrm{A})+H R-H E(D)-(\pi+H) \int_{R}^{\infty} R f(x) d x
\]
\[
+(\pi+H) \int_{R}^{\infty} x f(x) d x \Rightarrow
\]

Finally:
\[
E(Y)=P(R-\mathrm{A})+H(R-E(D))+(\pi+H) \int_{R}^{\infty}(x-
\] R) \(f(x) d x\).

Average profit is given by:
\[
\begin{aligned}
& E(Z)=E(U)-E(Y) \\
& \begin{aligned}
& E(\mathrm{U})=V E(D)+V \int_{R}^{\infty}(R-x) f(x) d x \\
& E(Z)=V E(D) \\
& \\
&+V \int_{R}^{\infty}(R-x) f(x) d x-P(R-\mathrm{A})-H R
\end{aligned} \\
& \quad+H E(D)- \\
& (\pi+H) \int_{R}^{\infty}(x-R) f(x) d x
\end{aligned}
\]
\[
E(Z)
\]
\[
=\underbrace{(V+H) E(D)}_{\text {does not depend on } R}
\]
\[
-\underbrace{\left[P(R-\mathrm{A})+H R+(V+\pi+H) \int_{R}^{\infty}(x-R) f(x) d x\right]}
\]

Now let
\[
\begin{equation*}
K(R)=P(R-A)+H R+(V+\pi+H) \int_{R}^{\infty}(x-R) f(x) d x \tag{5-8}
\end{equation*}
\]

Then
\[
E(Z)=\underbrace{(V+H) E(D)}_{\text {does not depend on } R}-K(R)(5-9)
\]

Our objective is to determine a value for R which maximizes \(E(Z)\) or equivalently minimizes \(K(R)\) which plays a significant role in the cost of
this model. Note that \(\frac{\partial^{2} K(R)}{\partial R^{2}}=(V+\pi) H f(R)\) is the product of 3 non- negatives then \(\frac{\partial^{2} K(R)}{\partial R^{2}} \geq 0\). Therefore \(K(R)\) has minimum. Figure 5.1 shows a typical function \(K(R)\) and its minimum

Fig 5.1 A typical function \(K(R)\)

\section*{Example 5.1}

In a single period decision model \(P=0.2, A=0, V=2, \pi=0\), \(H=0.1\) and

If the demand for the period is uniformly distributed over [10,20], draw the function \(\mathrm{K}(\mathrm{R}), 10<R<45\),

If the demand for the period is normally distributed with mean 20 and variance 9 , draw the function \(\mathrm{K}(\mathrm{R}), 0<R<20\),

\section*{Solution}
a)
\(K(R)=P(R-A)+H R+(V+\pi+H) \int_{R}^{\infty}(x-R) f(x) d x\)
\(P=0.2, A=0, V=2, \pi=0, H=0.1, f(x)=\frac{1}{20-10}, x \in[1020]\),
\[
\begin{aligned}
K(R)=0.2(R & -0)+0.1 R \\
& +(2+0+0.1) \int_{x=R}^{20}(x-R) \frac{1}{10} d x \\
& =0.3 \mathrm{R}+\frac{2.1}{40}(30-R)^{2}
\end{aligned}
\]

The following command in MATLAB draws Fig 5.2:
\(\mathrm{R}=10: .01: 45 ; \mathrm{K}=.3^{*} \mathrm{R}+2.1^{*}(30-\mathrm{R}) .^{\wedge} / 40 ; \mathrm{plot}(\mathrm{R}, \mathrm{K})\)

Fig 5-2 Function \(\mathrm{K}(\mathrm{R})\) for Example 5.1 (uniform demand)
b)

Substituting the data yields
\(K(R)=0.3 R+2.1 \int_{R}^{\infty}(x-R) f(x) d x\)
Where \(f(x)\) is the pdf of a normal distribution with \(\mu=20 \& \sigma=3\).
According to Eq. 5-1 in Sec. 1.5.1 we could write
\(\int_{R}^{\infty}(x-R) f(x) d x=\sigma \mathrm{G}_{\mathrm{U}}(\mathrm{k}) \quad \mathrm{k}=\frac{\mathrm{R}-\mu}{\sigma}\)
Where
\(\mathrm{G}_{\mathrm{U}}(\mathrm{k})\) is given by Table A at the end of the book or by the following MATLAB command:
\[
\left.\mathrm{G}_{\mathrm{U}}(\mathrm{k})=\exp (-\mathrm{k} \cdot \wedge \uparrow / \Upsilon) / \operatorname{sqrt}\left({ }^{\wedge} * \mathrm{pi}\right)-\mathrm{k} \cdot{ }^{*}()-\operatorname{normcdf}(\mathrm{k})\right)
\]

Then \(K(R)=0.3 R+2.1 \sigma \mathrm{G}_{\mathrm{U}}\left(\frac{\mathrm{R}-20}{3}\right)\).
Fig 5.3 is the plot of \(K ®\) versus \(R\) drawn by the following MATLAB commands:
\(\mathrm{R}=0: .01: 20 ; \mathrm{k}=(\mathrm{R}-20) / 3\);
\(\mathrm{KR}=.3 * \mathrm{R}+2.1 * 3 * \exp (-\mathrm{k} . \wedge 2 / 2) / \mathrm{sqrt}(2 * \mathrm{pi})-\mathrm{k} . *(1-\mathrm{normcdf}(\mathrm{k})) ; \mathrm{plot}(\mathrm{R}, \mathrm{KR})\)

Fig 5-3 Function \(\mathrm{K}(\mathrm{R})\) for Example 5.1(normal demand )

\section*{5-2-1-1-1 Optimal value of maximum inventory \(\left(R^{*}\right)\)}

We are in search of that value of maximum inventory (R) which maximizes the profit \(E(Z)\) or that value of \(R\) which satisfy \(\frac{d E(Z)}{d R}=0\).
\(\frac{d E(Z)}{d R}=0 \Rightarrow-P-H+(V+\pi+H) \int_{R}^{\infty} f(x) d x=0 \quad \Rightarrow\)
\(P+H-(V+\pi+H)\left[1-F\left(R^{*}\right)\right]=0 \quad \Rightarrow\)
If demand is continuous, the optimal value of R is derived from:
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 236 \\
\hline
\end{tabular}
\[
\begin{equation*}
F\left(R^{*}\right)=\frac{V+\pi-P}{V+\pi+H} \tag{5-10}
\end{equation*}
\]

The answer exists if \(0 \leq \frac{\mathrm{V}+\pi-\mathrm{P}}{\mathrm{V}+\pi+\mathrm{H}} \leq 1\) and shortage is allowed.
Note that
-The differentiation under integral sign has used Leibniz's Rule. According to this rule if \(F(y)=\int_{g(y)}^{h(y)} f(x, y) d x\), then
\(F^{\prime}(y)=h^{\prime}(y) f(h(y), y)-g^{\prime}(y) f(g(y), y)+\int_{g(y)}^{h(y)} \frac{\partial f(x, y)}{\partial y} d x\).
-the difference V-P is the profit of one unit,
-If the distribution of consumption during the period is denoted by X then

Shortage probability for the period= \(\operatorname{Pr}\left(\mathrm{X}>R^{*}\right)=1-\) \(F\left(R^{*}\right)\).
-What is sometimes called service level is equal to:
\[
\text { Service level } p=\operatorname{Pr}\left(\mathrm{X} \leq R^{*}\right)
\]

\section*{5-2-1-1-2 Optimal strategy in single period model}

If \(A \geq R^{*}\) i.e. the inventory level before placing an order is greater than or equal to \(R^{*}\), no order is placed; and if \(A<R^{*}\) an order is placed with the quantity
\[
\begin{equation*}
\mathrm{Q}^{*}=\mathrm{R}^{*}-\mathrm{A} \tag{5-11}
\end{equation*}
\]

Needless to say that A is deducted from \(\mathrm{R}^{*}\) only if the units are usable for the period ad are not things such as newspaper which is not usable for the coming period .

\section*{Some comments:}
-When \(\pi=0\) we have \(F\left(R^{*}\right)=\frac{V-P}{V+H}\). In this case it obvious that there exists an answer for \(R^{*}\) only if \(\mathrm{V} \geq \mathrm{P}\) which is economically true.
- When the range of the demand is restricted to interval \(\left[\begin{array}{ll}a & b] \text {, if } F\left(R^{*}\right)= \\ \hline\end{array}\right.\) 1 then set \(\mathrm{R}^{*}=\mathrm{b}\); if a negative value was calculated for \(\mathrm{F}\left(\mathrm{R}^{*}\right)\) set \(R^{*}=a\) and if shortage is not permitted in the model ( \(\pi=\) \(\infty)\) then \(F\left(R^{*}\right)=1\) and \(R^{*}=b\).

\section*{5-2-1-1-3 average shortage cost in the single period model}

Shortage occurs when the demand over the period (X) exceeds R; other wise we would not face with shortage and we have no cost incurred due to shortage.
\[
\text { unit shortage cost }=\left\{\begin{array}{cc}
\pi & \operatorname{Pr}(X>R) \\
0 & \operatorname{Pr}(X \leq R)
\end{array}\right.
\]

The expected value of shortage cost \(=\)
\[
\pi \times \operatorname{Pr}(X>R)+0 \times \operatorname{Pr}(X \leq R)=\pi \times \operatorname{Pr}(X>R)
\]

\section*{Example 5-2}

The weekly demand of a kind of liquid follows a Weibul distribution with parameters \(\mathrm{A}=0, \mathrm{~B}=1000\) lit \(\mathrm{C}=2\). If the liquid is not consumed within a week, it would be considered salvage and no one buys it and its cost of dis- posal is \(\$ 0.1\) per one liter unsold. There no shortage cost except the lost profit. The liquid is bought \(\$ 0.2\) per liter and sold \(\$ 2\) per liter. Find the opti- mal order quantity.

\section*{Solution}
\[
\begin{gathered}
\text { Weekly } D \sim \operatorname{weib}(B=1000, C=2) \quad P=\frac{0}{2}, V=2, \quad \pi=0, \\
H=H^{\prime}-L=0.1-0=0.1
\end{gathered}
\]

\section*{Chapter 5 Inventory control under uncertainty 238}
\[
\begin{aligned}
& F\left(R^{*}\right)=\frac{V+\pi-P}{V+\pi+H}=\frac{2+0-0.2}{2+0+0.1}=\frac{1.8}{2.1} \Rightarrow \\
& 1-e^{-\left(0.001 R^{*}\right)^{2}}=\frac{1.8}{2.1}=0.8571 \Rightarrow R^{*} \cong 1392
\end{aligned}
\]

Or with MATLAB:
\[
\begin{aligned}
& R^{*}=\operatorname{wblinv}(.8571,1000,2)=1392 \\
& \mathrm{Q}^{*}=\mathrm{R}^{*}-\mathrm{A} \quad=1392-\cdot=1392
\end{aligned}
\]

\section*{Example 5-3}

In a one period model an item is sold \(\$ 20\) per unit where the unit pur- chase price is \(\$ 12\). Shortage incur no cost except the lost profit. The unsold units have no value and cost at the end of the period. there is 5 units available at the beginning of the period. Find the optimal order quantity for the following cases:
a)The demand of the item in the one period model follows a uniform distribution over \((0,100)\)
b) The demand is exponentially distributed with parameter \(\lambda=0.01\).

\section*{Solution}

In this problem there is no shortage cost i.e. \(\pi=0\), since there is no cost except the lost profit and \(\mathrm{H}^{\prime}=0 \& \mathrm{~L}=0\) since there is not any cost and revenue for the unsold units
\[
F\left(R^{*}\right)=\frac{V+\pi-P}{V+\pi+H}=\frac{20+0-12}{20+0+0}=0.4
\]
a)For the uniform distribution:
\[
\begin{aligned}
F(x) & =\frac{x-0}{100-0} \\
F\left(R^{*}\right) & =0.4 \Longrightarrow \frac{R^{*}-0}{100-0}=0.4 \Longrightarrow R^{*}=40
\end{aligned}
\]
optimal order quantity \(=Q^{*}=\left(\mathrm{R}^{*}-\mathrm{A}\right)=40-5=35\).
b)
\[
1-e^{-0.01 R^{*}}=0.4 \quad R^{*}=\operatorname{expinv}(0.4,100)==51
\]

Optimal order quantity \(=51-5=46\)

\subsection*{5.2.1.2 Single period Inventory model : \(C_{o} \cong 0 \&\) discrete demand}

In this section the above single-period model is retreated under assumption that the demand for the period is not continuous and the setup/order cost is negligible. In this case relationships similar to those developed for continuous demand case are obtained. The difference lies on the use of sigma sign ( \(\Sigma\) )sign instead of integral \(\operatorname{sign}\left(\int \quad\right)\) :
\(K(R)=P(R-I)+H R+(V+\pi+H) \sum_{x=R+1}^{\infty}(x-R) P_{X}(x)\)
\[
\Delta K(R)=K(R+1)-K(R) \Longrightarrow
\]
\[
\Delta K(R)=P+H+(V+\pi
\]
\[
+H)\left\{\left[\sum_{x=R+2}^{\infty}(x-R-1) P_{X}(x)\right]\right.
\]
\[
\left.-\left[\sum_{x=R+1}^{\infty}(x-R) P_{X}(x)\right]\right\} \Rightarrow
\]
\[
\begin{aligned}
& \Delta K(R)=P+H+(V+\pi+H)\left\{\left[P_{X}(R+2)+2 P_{X}(R+3)+\right.\right. \\
& \left.\left.3 P_{X}(R+4)+\cdots\right]-\left[P_{X}(R+1)+2 P_{X}(R+2)+3 P_{X}(R+3)+\cdots\right]\right\} \\
& \Delta K(R)=\mathrm{P}+\mathrm{H}+(V+\pi+H)\left\{-P_{X}(R+1)-P_{X}(R+2)-P_{X}(R+3)-\cdots\right\}
\end{aligned}
\]
\(\Delta K(R)=P+H-(V+\pi+H) P_{X}(X>R)\)
We would like to minimize the discrete function \(K(R)\). Assuming \(\Delta K(R) \geq 0\) we could write:
\[
\Delta K(R)=P+H-(V+\pi+H) P_{X}(X>R) \geq 0
\]
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 240 \\
\hline
\end{tabular}
\(P_{X}(X>R)\) or \(\operatorname{Pr}(D>R) \leq \frac{P+H}{V+\pi+H} \Rightarrow\)
\(1-\operatorname{Pr}(D>R) \geq 1-\frac{P+H}{V+\pi+H}\) or \(F(R) \geq 1-\frac{P+H}{V+\pi+H}\)
Where \(F(R)\) is the cumulative distribution function of demand.
The best value of R denoted by \(R^{*}\) is the smallest R value which satisfies the following inequality(based on Peterson \&Silver, 1991 page 395)

Discrete demand \(\quad F(R) \geq \frac{V+\pi-P}{V+\pi+H}\)
This \(R^{*}\) minimizes the cost function \(K(R)\).

\section*{Optimal Policy}
\(R^{*}\) is the smallest R value which satisfies
If \(A \geq R^{*}\) i.e. the inventory level before placing an order is greater than or equal to \(R^{*}\), no order is placed; and if \(A<R^{*}\) an order is placed with the quantity \(\mathrm{Q}^{*}=\mathrm{R}^{*}-\mathrm{A}\).

\section*{Example 5-4}

A single-period item is bought \(\$ 3000\) per unit and sold \(\$ 5000\) per unit; There is no shortage cost except the lost profit. The actual holding cost of one unsold item is \(\mathrm{H}^{\prime} \approx 0\) i.e. negligible. The sale cost at the end of the period is: \(\mathrm{L}=2000\).

The demand is discrete with the probabilities given below:
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|}
\hline demand & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 \\
\hline Prob. & 0.05 & 0.05 & 0.1 & 0.2 & 0.2 & 0.2 & 0.1 & 0.05 & 0.05 \\
\hline
\end{tabular}

Find the optimal order quantity and the probability of shortage.

\section*{Solution}
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|}
\hline D or X & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 \\
\hline Probability & \[
0
\] & o & \(\bigcirc\) & is & i & i & \(\bigcirc\) & \[
0
\] & - \\
\hline \(F_{D}(x)\) & o & \(\bigcirc\) & is & \[
i
\] & \[
\dot{8}
\] & \[
0
\] & \[
0
\] & io & \(\checkmark\) \\
\hline \multicolumn{10}{|l|}{the smallest value which satisfies \(F_{D}(\mathrm{R}) \geq \frac{V+\pi-P}{V+\pi+H}\)} \\
\hline
\end{tabular}

Since there is no shortage cost then \(\pi=0\).
\[
H=H^{\prime}-L=0-2000
\]

Shortage probability \(=\)
\[
\begin{aligned}
& \operatorname{Pr}\left(X>R^{*}\right)=1-F_{D}\left(R^{*}\right)=\frac{P+H}{V+\pi+H}=\frac{3000-2000}{5000-2000}=\frac{1}{3} \\
& F_{D}\left(R^{*}\right) \geq \frac{V+\pi-P}{V+\pi+H}=\frac{5000+0-3000}{5000+0-2000}=0.66
\end{aligned}
\]

The smallest value which satisfies \(F_{D}\left(R^{*}\right) \geq 0.66\) is the answer.
According to the table \(R^{*}=11\).

\subsection*{5.2.2 Single Period Model -order/setup cost ( \(\mathbf{C}_{0}\) ) considerable}

In this section the single-period model is studied subject to nonzero order/setup cost

\section*{Symbols}

A inventory level at the beginning of the period
R inventory level after receipt of the order
\(\mathrm{r}_{0} \quad\) The smallest root of \(P r_{0}+L\left(r_{0}\right)-C_{o}-P R_{0}-L\left(R_{0}\right)=0\)
\(L(R) \quad L(R)=H R+(V+\pi+H) \int_{R}^{\infty}(x-R) f(x) d x\)
\(K^{\prime}(R) \quad K^{\prime}(R)=P R+L(R)\)
The point where functions \(K(R), K^{\prime}(R)\) are minimized derived
\(\mathrm{R}_{0} \quad\) from \(F\left(R_{0}\right)-\frac{V+\pi-P}{V+\pi+H}=0\)
\(\mathrm{L}(\mathrm{A}) \quad\) The cost during the period if no order is placed
Chapter 5 Inventory control under uncertainty 242

In the previous section where order/setup cost was negligible ( \(C_{o} \cong 0\) ). \(\mathrm{K}(\mathrm{R})\) in the relationship given for profit sometimes equals the cost which we want to minimize. In this section the cost including the order/setup cost \(C_{o}\) would be:

If \(\mathrm{R}<\mathrm{A}\) no order is placed no calculations is needed.
If \(\mathrm{R} \geq \mathrm{A}\),the cost of period equals \(C_{o}\) as well as the cost in the previous section i.e. \(K(R)=P(R-A)+L(R)\) where
\(L(R)=H R+(V+\pi+H) \int_{R}^{\infty}(x-R) f(x) d x\)
Then the cost of the period: \(C_{O}+K(R)=C_{O}+P(R-I)+\) \(\underbrace{H R+(V+\pi+H) \int_{R}^{\infty}(x-R) f(x) d x}_{L(R)}\)

If we let \(K^{\prime}(R)=P \times R+L(R)\) then the cost of period \(=\)
\[
C_{o}+P(R-A)+L(R)=C_{o}+P \times R+L(R)-P A=C_{O}+K^{\prime}(R)-P A
\]

Now let focus on function \(K^{\prime}(R)\) which plays a major role in the cost
\[
K(R)=K^{\prime}(R)-P A \quad \rightarrow \quad K^{\prime}(R)=K(R)+P A
\]

The product of the unit price and the inventory at the beginning of the period \((\mathrm{A})\) is positive, then if \(R_{0}\) is the point at which the minimum of \(K(R)\) occurs, the minimum of function \(K^{\prime}(R)\) occurs at the same point \(\mathrm{R}_{0}\). Now note that when \(\mathrm{R}=\mathrm{A}\), no order is placed i.e. \(C_{O}=0\). Substituting \(C_{O}=0 \& R=A\) in the above relationship yields the cost of the inventory system when \(R=A\).
the cost of period \(=C_{o}+P(R-A)+L(R)\)
The cost for \((\mathrm{R}=\mathrm{A})=\)
\(0+P(A-A)+H I+(V+\pi+H) \int_{I}^{\infty}(x-A) f(x) d x\)
Denoting the above cost with L(I), we could write:
\[
L(A)=H A+(V+\pi+H) \int_{I}^{\infty}(x-A) f(x) d x
\]

The following figure shows an example of the function
\(K^{\prime}(R)=P R+L(R) . \mathrm{R}\) is on the horizontal axis and \(K^{\prime}(R)\) on the vertical axis.

Fig. 5.4 A typical plot of function \(K^{\prime}(R)=P R+L(R)\)
The minimum of function \(K^{\prime}(R)\) happens at the same point where \(K(R)\) is minimized i.e. a point such as \(R_{0}\) derived from \(F\left(R_{0}\right)-\frac{V+\pi-P}{V+\pi+H}=0\).

Assume point \(r_{0}\) be that value of R that minimizes \({ } \mathrm{C}_{0}+\) \(K^{\prime}(R)\) ". The minimum of \(K^{\prime}(R)\) is \(K^{\prime}\left(R_{0}\right)\) then the" minimum of \(\mathrm{C}_{\mathrm{O}}+\mathrm{K}^{\prime}(\mathrm{R})\) " is " \(\mathrm{C}_{\mathrm{O}}+\mathrm{K}^{\prime}\left(R_{0}\right)\) ". As Fig \(5-4\) shows this value on the vertical corresponds to 2 values on the horizontal axis; however, the smaller value is of our interest in this case. Another words \(r_{\mathrm{o}}\) the smallest value ( \(r_{\mathrm{o}}<R_{\mathrm{o}}\) ) which satisfies:
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 244 \\
\hline
\end{tabular}
\(C_{O}+P \mathrm{R}_{\mathrm{o}}+L\left(\mathrm{R}_{\mathrm{o}}\right)=K\left(\begin{array}{c}\left.r_{0}\right)=P^{r_{0}}+L\left(r_{0}\right) . . . . . . . . . . .\end{array}\right.\)
\(r_{0}\) and the inventory at the beginning of the period(A) play a role in determining the optimal policy in this case. 3 states are distinguished here:

\section*{State I: \(\mathbf{A}>\mathbf{R}_{\mathbf{o}}\)}

Substituting \(R=\mathrm{A}\) in \(K^{\prime}\) yields \(P A+L(\mathrm{~A})\). Referring to Fig 5.5 it is obvious that \(K^{\prime}(R)=P R+L(R)>P A+L(A)\). Adding the positive number \(\mathrm{C}_{\mathrm{O}}\) to the both sides does not change the direction of the inequality symbol: \(C_{O}+P R+\) \(L(R)>P A+L(A) \Rightarrow C_{O}+P(R-A)+L(R)>L(A)\)

The right had side of the inequality is the cost of the inventory system when no order us placed and the left hand of the inequality when \(\mathrm{A}<\mathrm{R}\) and an order of size \(\mathrm{R}-\mathrm{A}\) is placed. Since the latter cost is greater the former cost, then we have to place no order.

Fig 5.5 Single -period model \(C_{O} \neq 0\) and \(\mathrm{A}>\mathrm{R}_{\mathrm{o}}\)
State II: \(\mathbf{r}_{\mathbf{o}} \leq \mathrm{A} \leq \mathbf{R}_{\mathbf{o}}\) for \(\mathbf{R}>\mathrm{A}\)
With the assumption \(C_{O}+K^{\prime}\left(R_{0}\right)>K^{\prime}(\mathrm{A})\)

For any R in the interval \(r_{0}<I<R \leq R_{0}\) (Fig. 5.6) we could write:

Fig 5-6 Single period model \(C_{O} \neq 0 \& r_{0} \leq \mathrm{A} \leq R_{0}\)
\(C_{O}+P R+L(R)>P A+L(A) \Rightarrow C_{O}+P(R-A)+L(R)>L(A)\)
The right hand side of the lat inequality the cost of the inventory system if no order is placed. Again here ( \(r_{0}<A<R_{0}\) ) the cost of the inventory system if no order is placed is less than the cost if an order is placed; then we have to place no order.

Note since practically \(R \not \subset A\) the state \(r_{0}<R<A \leq R_{0}\) is not applicable.

State III \(\boldsymbol{A}<\boldsymbol{r}_{\boldsymbol{o}}\) (Fig 5.7)

Fig 5-7 State III(A< \(\boldsymbol{r}_{\boldsymbol{o}}\) in single period model having \(\boldsymbol{C}_{\boldsymbol{o}}\)
Remembering the definition of \(r_{o}\), in this state \(K^{\prime}(A)>K^{\prime}\left(r_{0}\right)\). Referring to Fig 7-5 we could write:
\[
\begin{aligned}
& \quad P R_{0}+L\left(R_{0}\right)=K^{\prime}\left(R_{0}\right), P r_{0}+L\left(r_{0}\right)=K^{\prime}\left(r_{0}\right) \\
& K^{\prime}\left(r_{0}\right)<K^{\prime}(A) \\
& C_{O}+P R_{0}+L\left(R_{0}\right)=P r_{0}+L\left(r_{0}\right) \\
& P r_{0}+L\left(r_{0}\right)<P I+L(A) \Rightarrow \\
& C_{O}+P R_{0}+L\left(R_{0}\right)<P A+L(A) \\
& C_{O}+P\left(R_{0}-A\right)+L\left(R_{0}\right)<L(A)
\end{aligned}
\]

The right hand side of the lat inequality is the cost of the inventory system when no order is placed which was previously calculated. The left hand side is the cost when an order is placed with size \(R_{o}-A\). Therefore if we place an order our cost decreases .

\section*{Optimal strategy for single period Model having order cost}

\section*{If \(\mathbf{A} \geq \mathbf{r}_{0}\) place no order,}
where
A is the inventory at the beginning of the period,
\(r_{0}\) is the smallest root of the following equation solved for \(r_{0}\) :
\[
\begin{equation*}
P r_{0}+L\left(r_{0}\right)-C_{O}-P R_{0}-L\left(R_{0}\right)=0 \tag{5-12}
\end{equation*}
\]
\(R_{0}\) is the point where the function \(K(R)+P A\) or \(K^{\prime}(R)=\) \(P R+L(R)\) is minimized.; it is obtained from:
\[
\begin{gather*}
F\left(R_{0}\right)-\frac{V+\pi-P}{V+\pi+H}=0  \tag{5-13}\\
L\left(R_{0}\right)=H R_{0}+(V+\pi+H) \int_{R}^{\infty}\left(x-R_{0}\right) f(x) d x
\end{gather*}
\]
\(f(x)\) is the probability density function of the demand.
If \(\mathbf{A}<\mathbf{r}_{\mathbf{0}}\), place an order of size
\[
\begin{equation*}
\mathrm{Q}=\mathrm{R}_{0}-\mathrm{A} \tag{5-15}
\end{equation*}
\]

This is a kind of the so-called continuous review policy denoted by ( \(\mathrm{r}, \mathrm{Q}\) ) which is frequently used in industry.

\section*{Example 5-5}

An item is sold in a single period. The unit purchase and selling prices are \(\$ 12\) and \(\$ 20\) respectively. Shortage cause no cost except lost profit. The unsold units at the end of the period have no cost and no revenue. The demand for the period is uniformly distributed over \((0,100)\). The initial inventory is 5 useable units. Find the optimal order strategy if the fixed order cost is a) \(\mathrm{C}_{\mathrm{O}}=160\) b) \(\mathrm{C}_{\mathrm{O}}=200\).

\section*{Solution}

We have to find \(R_{0}\) and \(r_{0}\) :
\[
F\left(R_{0}\right)=\frac{V+\pi-P}{V+\pi+H}
\] \(\pi=0\) since no shortage cost is incurred.
\[
V=20, \mathrm{P}=12, \mathrm{~L}=0, H^{\prime}=0
\]
\[
H=H^{\prime}-L=0-0=0
\]
\[
F\left(R_{0}\right)=\frac{V+\pi-P}{V+\pi+H}=\frac{20+0-12}{20+0+0} \Rightarrow F\left(R_{0}\right)=0.4
\]

Since the demand is uniformly distributed on the interval [0 100] then
\(F\left(R_{0}\right)=\frac{R_{0}-0}{100-0} \Rightarrow 0.4=\frac{R_{0}}{100} \Rightarrow R_{0}=40\).
To find \(r_{0}\) for part (a) we have to solve the following equation for \(r_{0}\) :
\[
\begin{aligned}
& P r_{0}+L\left(r_{0}\right)=C_{O}+P R_{0}+L\left(R_{0}\right) \\
& R_{0}=40 \quad \mathrm{P}=12 \quad C_{O}=160 \quad, L\left(R_{0}\right) \\
& L(R)=H R+(V+\pi+H) \int_{R}^{\infty}(x-R) f(x) d x
\end{aligned}
\]

The probability distribution function of a uniformly distributed demand is \(\frac{1}{100}\) ove \(\{0100)\)
\[
L\left(R_{0}\right)=(0)(40)+(20+0+0) \int_{40}^{100}(x-40)\left(\frac{1}{100}\right) d x=360
\]

To derive \(r_{0}\) we substitue \(\quad R=r_{0}\) in \(L(R)\) :
\[
\begin{aligned}
& L\left(r_{0}\right)=(0)\left(r_{0}\right)+(20+0+0) \int_{r_{0}}^{100}\left(x-r_{0}\right)\left(\frac{1}{100}\right) d x \\
& P r_{0}+L\left(r_{0}\right)=C_{0}+P R_{0}+L\left(R_{0}\right) \Longrightarrow \\
& 12 r_{0}+20 \int_{r_{0}}^{100}\left(x-r_{0}\right)\left(\frac{1}{100}\right) d x=160+4 * 12+360 \Rightarrow
\end{aligned}
\]
\(12 r_{0}+1000-20 r_{0}+\frac{r_{0}^{2}}{10}=1000 \Longrightarrow r_{0}=0,80\)
We have to choose the smallest root i.e. \(r_{0}=0\).
\(\mathrm{r}_{0}<A=5 \Longrightarrow\) no order is placed.
Solution of part \(b\) is similar to part \(a\) :
\[
\begin{aligned}
& P r_{0}+L\left(r_{0}\right)=C_{O}+P R_{0}+L\left(R_{0}\right) \Longrightarrow \\
& 12 r_{0}+20 \int_{r_{0}}^{100}\left(x-r_{0}\right)\left(\frac{1}{100}\right) d x=100+40 * 12+360 \Rightarrow \\
& 12 r_{0}+\left(1000-20 r_{0}+\frac{r_{0}^{2}}{10}\right)=100+480+360 \Rightarrow \frac{r_{0}^{2}}{10}-8 r_{0}+70=0 \\
& \text { MATLAB } \Rightarrow \mathrm{r}_{0}=\operatorname{roots}\left(\left[\begin{array}{lll}
0.1 & -8 & 70
\end{array}\right]\right) \Rightarrow r_{0}=8.4,71.68
\end{aligned}
\]

The smallest root is 8.4
Since \(A<r_{0}=8.4\), an order of size \(Q=40-A=35\) has to be placed.End of example \(\boldsymbol{\Lambda}\)

\section*{Exercises}
1.(Tersine, 1994 page 327)

The Parker Flower shop promises its customers to deliver within 4 hours on all flower orders. All flowers are purchased on the previous day and delivered to Parker by \(8 \mathrm{a} . \mathrm{m}\). in the next morning. Parker's daily demand for roses is as follows:
\begin{tabular}{|l|l|l|l|l|}
\hline Dozens of roses & 7 & 8 & 9 & 10 \\
\hline Probability & 0.1 & 0.2 & .4 & 0.3 \\
\hline
\end{tabular}
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 250 \\
\hline
\end{tabular}

Parker purchases roses for \$ 10 per dozen and sells them at \$ 30 All unsold roses are donated to a local hospital. How many dozens of roses should parker order each evening to maximize its profits? What is the optimum expected profit?

\section*{2.(Tersine, 1994 page 228)}

You are having a new furnace installed. The dealer offers to sell you spare fuel pumps at \(\$ 20\) each if you buy them during installation. The pumps sell for \(\$ 50\) retail. Manufacturer records indicate the following probability of fuel pump failures during the furnace's lifetime.
\begin{tabular}{|l|l|l|l|l|l|}
\hline Failures & 0 & 1 & 2 & 3 & 4 \\
\hline Probability \(\%\) & 10 & 30 & 40 & 10 & 10 \\
\hline
\end{tabular}

Ignoring installation and holding cost, how many spare fuel pumps should be purchased during installation? What is the expected purchase cost?

\section*{Hint:}

Solve the problem with Single period model; treat the failures as demand and substitute \(P=20, V=50\).
3.(Extracted from Peterson \&Silver, 1991 page 418)

A local vendor of newspapers feels that dissatisfaction of customers leads to future lost sales. In fact, he feels that the average demand \((\mu)\) for a particular newspaper is related to the service level(p) as follows: \(\mu=100+p\). The demand is normally distributed and the standard deviation (per period) s equal to 200 , independent of the service level. The ordering cost is negligible and the other (possibly) relevant factors are:

Cost per paper (for vendor) \(=\mathrm{P}=\$ 0.07\)

Selling price per paper \(=\mathrm{V}=\$ 0.15\)

Salvage value per paper \(=\mathrm{L}=\$ 0.02, \quad \mathrm{H}^{\prime}=0\)

If shortage has no cost except lost profit,
a)What is the optimal value for maximum inventory ( R )
b)Solve Part a if the unit shortage cost is \(\$ 2\).
c) What average profit is the vendor losing if he proceeds as in (a) instead of as in (b)?

Hint: estimate of service level \(=\hat{p}=\operatorname{Pr}(X \leq R)\).
4. In a single period model similar to that of Example 5-5 The following data is available :
\begin{tabular}{|l|c|}
\hline The setup cost & \(C_{O}=5\) \\
\hline The demand is uniformly distributed over [0 100] & \(f(x)=0.01\) \\
\hline \begin{tabular}{l} 
The actual holding per unit remained at the end of \\
the period
\end{tabular} & \(H=3\) \\
\hline The production cost per unit & \(\mathrm{P}=1\) \\
\hline Unit shortage cost (lost profit not included) & \(\pi=2\) \\
\hline The unit selling price & \(\mathrm{V}=5\) \\
\hline
\end{tabular}

Find \(r_{0}, R_{0}\).
Ans: \(\mathrm{r}_{0}=5.9, \mathrm{R}_{0}=60\)
5. Given the following data in a single-period model, Find \(r_{0} \& R_{0}\). What is the optimal strategy,
\begin{tabular}{|l|c|}
\hline The ordering cost & \(C_{O}=800\) \\
\hline \begin{tabular}{l} 
The demand is exponentially distributed with mean \\
10000 units
\end{tabular} & \(f(x)=0.01\) \\
\hline The actual holding cost per unit unsold at the end of the period & \(H=-9\) \\
\hline The purchase cost per unit & \(\mathrm{P}=20\) \\
\hline Unit shortage cost (lost profit not included) & \(\pi=0\) \\
\hline The unit selling price & \(\mathrm{V}=45\) \\
\hline
\end{tabular}

Ans : \(\mathrm{r}_{0}=10674, \mathrm{R}_{0}=11856\)
If \(A<r_{0}\) Place an order of size \(R_{0}-A\) to minimize cost.
If \(A>r_{0}\) No order is placed.

\section*{Chapter 5 Inventory control under uncertainty 252}

\subsection*{5.3 Probabilistic Continuous and Periodic review models- introduction}

A continuous review system, which is sometimes called a fixed order size system, is one in which inventory is monitored at a continuous rate and whenever the inventory reaches a value such as \(\boldsymbol{r}\) an order of size say Q is placed. The symbol for this model is FOS and ( \(r\) Q). In periodic review model stock is reviewed at fixed and specific intervals of time (say every T days ), and an order is placed with the quantity necessary to achieve the desired maximum inven-tory denoted here by R. The later model is denoted by \(\mathrm{FOI}=(\mathrm{R}, \mathrm{Q})\). Some of the applications of these 2 models are:
-FOS is advised for contingency stocks as demand is usually highly unpredictable and also may be used for expensive items and those which need precise control.
- FOI may be applied to items with more regular demand.
- whenever several items have to be ordered from the same provider, FOI system is advised.

Note that:
-Shortage probability in FOI policy is less than that in FOS.
At a fixed service level ( \(\mathrm{p}=1\) - shortage probability) the safety stock, the average shortage level and the average inventory level in FOI. policy is more than those in FOS and also the shortage cost.
-Classic EOQ model is both ( \(R, T\) ) and ( \(r, Q\) ).
-Due to more safety stock, the holding cost in FOI policy is more than that in FOS policy.

In ( \(\mathrm{R}, \mathrm{T}\) ) policy the order quantity is more than that in ( r Q); therefore when the ordering cost \(\left(C_{o}\right)\) is high it is advised to use ( \(\mathrm{R}, \mathrm{T}\) ) policy and when \(C_{o}\) is low, ( r Q ) is advised.
- In (r Q) policy ,the order quantity is fixed and the cycle time ( \(T\) ) is variable while in ( \(\mathrm{R}, \mathrm{T}\) ) policy the cycle time is fixed and the order quantity is variable.

Before giving more details about the two probabilistic models, some definitions are reminded below.

\section*{Definitions}

\section*{5-3-1 Safety stock}

Safety stock is an extra quantity held in the inventory by a retailer or a manufacturer to cope with unexpected increase of demand and the variation of lead time.

\section*{5-3-2 Service Level}

The service level represents the desired probability of not getting a stock-out during the lead time(TL) in other words the probability that the amount of stock during the TL is sufficient to meet expected demand. The more this probability which is dented by p , the less the probability of stockout, which equals 1p and sometimes called risk level.

At a fixed, the following values in FOS policy are less those in FOI system: the average shortage level, the holding cost and the shortage cost.

\section*{Theorem 5-1:The relationships for mean and variance of the lead time demand}

If in FOS policy, the demand \((\mathrm{D})\) and lead time \(\left(\mathrm{T}_{\mathrm{L}}\right)\) are independent random variables with mean and variance ( \(\mu_{D}\)
,\(\left.\sigma_{\mathrm{D}}^{2}\right),\left(\mu_{\mathrm{L}}, \sigma_{\mathrm{L}}^{2}\right)\) respectively then, regardless of their statistical distributions, the following relationship hold:
\[
\operatorname{Var}\left(D_{L}\right)=\mu_{D}^{2} \sigma_{L}^{2}+\mu_{L} \sigma_{D}^{2}
\]

Furthermore if D and \(\mathrm{T}_{\mathrm{L}}\) are independent or at least un correlated, then \(E\left(D_{L}\right)=\mu_{D} \mu_{L}\).

\section*{Proof of the first relationship}

Let divide \(D_{L}\) the consumption during the lead time \((\mathrm{L})\), into L elements \(D_{i}, i=1,2, \ldots . L\), with mean \(E\left(D_{i}\right)=\mu_{D}\) and variance \(\operatorname{Var}\left(D_{i}\right)=\sigma_{D}^{2}\). Then \(X=D_{L}=\sum_{i=1}^{L} D_{i}\). If the lead time is a random variable with mean \(\mu_{L}=\mathrm{E}(\mathrm{L}) \&\) variance \(\operatorname{Var}(L)=\sigma_{L}^{2}\) then assuming \(D_{i}^{\prime} s\) are independent and using the equality \(\operatorname{Var}(\mathrm{X})=\mathrm{E}(\operatorname{Var}(\mathrm{X} \mid \mathrm{Y})+\operatorname{Var}[\mathrm{E}(\mathrm{X} \mid \mathrm{Y})])\) we could write:
\[
\begin{gathered}
\operatorname{Var}(X)=\operatorname{Var}\left(\sum_{i=1}^{L} D_{i}\right)=E\left[\operatorname{Var}\left(\sum_{i=1}^{n} D_{i} \mid n=L\right)\right]+\operatorname{Var}\left[E\left(\sum_{i=1}^{n} D_{i} \mid n=L\right)\right] \\
=E\left(L \sigma_{D}^{2}\right)+\operatorname{Var}\left(L \mu_{D}\right) \Longrightarrow
\end{gathered}
\]

Now assuming the demand (D)and the lead time ( \(\mathrm{L}=\mathrm{T}_{\mathrm{L}}\) ) are independent
\[
\operatorname{Var}\left(\mathrm{D}_{\mathrm{L}}\right)=\mu_{\mathrm{L}} \sigma_{\mathrm{D}}^{2}+\mu_{\mathrm{D}}^{2} \sigma_{\mathrm{L}}^{2} \quad \text { or } \sigma_{D_{L}}=\sqrt{\mu_{D}^{2} \sigma_{L}^{2}+\mu_{L} \sigma_{D}^{2}} .
\]

\section*{End of proof ■}

Note that
- the above relationship is valid regardless of the statistical distributions of the demand and the lead time.
-when either the demand (D) or the lead time (L) is not random variable zero is substituted for the its standard deviation.

\section*{Theorem 5-2:}

If in FOI policy, the demand \((\mathrm{D})\) and lead time \(\left(\mathrm{L}=\mathrm{T}_{\mathrm{L}}\right)\) are independent random variables with mean and variance ( \(\mu_{\mathrm{D}}\) ,\(\left.\sigma_{\mathrm{D}}^{2}\right),\left(\mu_{\mathrm{L}}, \sigma_{\mathrm{L}}^{2}\right)\) respectively then, regardless of their statistical distributions, the following relationships are hold for the variance and mean of the quantity consumed during \(\mathrm{T}+\mathrm{L}\) :
\(\operatorname{Var}\left(D_{L+T}\right)=\mu_{T+L} \sigma_{D}^{2}+\mu_{D}^{2} \sigma_{T+L}^{2}\)
The proof is similar to that presented in Theorem 5-1.
Furthermore if D andL \(=\mathrm{T}_{\mathrm{L}}\) are independent or at least uncorrelated, then \(E\left(D_{L+T}\right)=\left(\mu_{D}\right)\left(\mu_{L+T}\right)\).

End of theorem
Note the above two relationship are valid, regardless the type of the statistical distributions of D and \(\mathrm{L}+\mathrm{T}\).

\subsection*{5.4Continuous Review Inventory Model \\ or (r, Q ) policy or FOS system}

This section deals with continuous review inventory systems which is denoted by ( \(\mathrm{r}, \mathrm{Q}\) ) or FOS.

\section*{Symbols}
\(b(x) \quad\) Bereft function in each cycle
\(\bar{b}(r) \quad\) Average shortage in each cycle
\(\bar{B}(r) \quad\) Average shortage per year
\(X=\quad\) The demand(consumption) during \(T_{L}\)
\(D_{L}\)
\(E\left(D_{L}\right) \quad\) Average consumption) during \(\mathrm{T}_{\mathrm{L}}\)
\(f_{D_{L}}(x)\) pdf of consumption during \(T_{L}\)
\(G_{U}(k) \quad\) Normal loss integral
\(m \quad\) Number of cycles per year
\(N_{b} \quad\) Average number of cycles with shortage per year
\(p \quad\) Service level, probability of lack of shortage
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 256 \\
\hline
\end{tabular}
\begin{tabular}{ll}
\(P\) & Purchase price \\
\(r\) & Reorder point \\
\(r *\) & Optimal reorder point \\
T & Cycle time \\
\(T_{b}\) & The mean time between "2 successive cycles with \\
V & shortage" \\
\(1-p\) & Selling price \\
\(\pi\) & Shortage probability in each cycle \\
\(\pi_{0}\) & Total shortage cost per unit \\
unit shortage cost (lost profit not included)
\end{tabular}

In continuous review policy denoted by ( \(\mathrm{r}, \mathrm{Q}\) ) or FOS, whenever the inventory reaches say \(r \mathrm{~m}\) an order or quantity Q is placed.

\subsection*{5.3.1 Order quantity in ( \(r, Q\) ) system}

In continuous review system, the order quantity might be determined based on the experience and judgment or from Wilson-Harris formula \(\mathbf{Q}=\sqrt{\frac{2 \mathbf{D C}_{\mathbf{0}}}{\mathbf{C}_{\mathbf{h}}}}\). If annual demand (D) is a random variable, its average i.e. \(\mathrm{E}(\mathrm{D})\) replaces D in the formula. Take note not to confuse \(\mathrm{E}(\mathrm{D})\) with \(\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)\), the average demand during the lead time.

\section*{5-3.2 Safety stock in (r,Q) system}

Let \(\mathrm{D}_{\mathrm{L}}\) denote the demand during the lead time and let \(r\) denote the reorder point; stockout occurs when \(D_{L}>r\). If the reorder point coincides the average demand during the lead time i.e. \(r=E\left(D_{L}\right)\) and no safety stock is available, after the time \(T_{L}\) has expired and just before arrival of the quantity ordered, it is expected that \(50 \%\) of the times we do encounter stockout and \(50 \%\) do not i.e. \(\mathrm{p}=\operatorname{Pr}\left(\mathbf{D}_{\mathbf{L}}<\boldsymbol{r}\right)=50 \%\) if the consumption during \(\mathrm{T}_{\mathrm{L}}\) is normally distributed.

> if the consumption during TL is exponentially distributed then \(\mathrm{p}=\) \(\operatorname{Pr}\left(\mathrm{D}_{\mathrm{L}}<r=\theta\right)=1-\mathrm{e}^{-\frac{\theta}{\theta}}=0.633, \operatorname{Pr}\left(\mathrm{D}_{\mathrm{L}}>r=\theta\right)=0.367\)

To reduce the risk of shortage or to increase the safety level (p) an amount known as safety stock \((\mathrm{SS})\) is added to \(\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)\), Therefore in this model
\begin{tabular}{|c|l|l|}
\hline Reorder point & \(\mathrm{r}=\mathrm{E}(\mathrm{DL})+\mathrm{SS}\) & \((5-16)\) \\
\hline Safety stock & \(\mathrm{SS}=\mathrm{r}-\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)\) & \((5-17)\) \\
\hline Max inventory & \(=\mathrm{r}+\mathrm{Q}\left(\right.\) if \(\left.\mathrm{T}_{\mathrm{L}}=0\right)\) & \((5-18)\) \\
\hline
\end{tabular}

Furthermore, the average holding cost equals \(\mathbf{C}_{\mathbf{h}} \times\left(\frac{\mathbf{Q}}{2}+\mathbf{S S}\right)\). The maximum demand that could be satisfied during \(\mathrm{T}_{\mathrm{L}}\) equals r. Therefore SS is an extra amount of inventory as well as \(\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)\) kept in reserve to make sure we satisfy the maximum demand and service level(p) and do not run out of stock i.e. SS \(=\mathrm{r}-\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)\). Let \(\boldsymbol{F}_{\boldsymbol{D}}\) denote the cumulative distribution function of consumption during \(\mathrm{T}_{\mathrm{L}}\) and assume the service level is p :
\(\mathrm{p}=\operatorname{Pr}\left(\right.\) no stockout during \(\left.\mathrm{T}_{\mathrm{L}}\right)\)
\[
\begin{equation*}
\mathrm{p}=\operatorname{Pr}\left(\mathrm{D}_{\mathrm{L}} \leq \mathrm{r}\right) \tag{5-19}
\end{equation*}
\]

Therefore
\[
\begin{align*}
& F_{D_{L}}(r)=p \quad \text { or } 1-\mathrm{p}=\operatorname{Pr}\left(D_{L}>r\right)=1-F_{D_{L}}(r) \\
& \quad \mathrm{p}=F_{D_{L}}(r) \rightarrow \mathrm{r}=F_{D_{L}}^{-1}(p)  \tag{5-20}\\
& S S=r-E\left(D_{L}\right)-(\mathrm{r}, \mathrm{Q}) \text { model } \tag{5-21}
\end{align*}
\]

Note :
Make sure that the variables have the same dimension when being substituted in the relationships. For example if the unit time given for one variable is month and for the other one is year, change both to year or both to month.

\section*{Example 5-6}

In an FOS policy the average consumption during the oneweek lead time is 45 and the desired service level is \(\mathrm{p}=95 \%\). Using the following figure find the reorder point and the necessary safety stock.

\section*{Solution}
\[
\begin{aligned}
& F_{D_{L}}(r)=p=0.95,1-F_{D_{L}}(r)=0.05 \xlongequal{\text { From figure }} r=90 \\
& S S=r-E\left(D_{L}\right)=90-45=45
\end{aligned}
\]

\section*{Example 5-7}

The demand for a product is uniformly distributed over [50 150]. Using a service level \(90 \%\) find the reorder and the safety stock.

\section*{Solution}

If \(\mathbf{X}\) is uniformlly dustributed over \([a b]\) then \(\mathbf{F}_{\mathbf{X}}(\mathbf{x})=\) \(\frac{\mathrm{x}-\mathrm{a}}{\mathrm{b}-\mathrm{a}}\).
\(\operatorname{Pr}\left(D_{L} \leq r\right)=0.9=F_{D_{L}}(r)\)
\(D_{L} \sim U(50,150) \Rightarrow F_{D_{L}}(r)=\frac{r-50}{100}=0.9 \quad \Rightarrow r=140\) units
\(E\left(D_{L}\right)=\frac{50+150}{2}=100, \quad S S=r-E\left(D_{L}\right)=140-100=40\)

\section*{Example 5-8}

A small shop uses FOS \(=(\mathrm{r}, \mathrm{Q})\) policy. The demand for a product during the lead time is approximately Poisson with mean 2 units. With a risk of \(2 \%\) find the reorder point and the safety stock. Furthermore if the annual demand is uniformly distributed over \(\left[\begin{array}{ll}0 & 10\end{array}\right]\) and \(C_{h}=4\) per year and the ordering cost is \(\$ 80\) per order. Find the optimal order quantity.

\section*{Solution}
\[
\begin{array}{cc}
1-p=0.02, & E\left(D_{L}\right)=2 \\
\operatorname{Pr}\left(D_{L} \leq r\right)=0.98, \lambda=2 &
\end{array}
\]

Using MATLAB command r=Poissinv(0.98,2)
or Poisson Table at the end of the book results in \(r=5\).
\(S . S=r-E\left(D_{L}\right)=5-2=3\)
\(E(D)=\frac{0+10}{2}=5 \quad Q^{*}=\sqrt{\frac{2 \times 5 \times 80}{4}} \Rightarrow \quad Q^{*} \cong 14\) -

\section*{Example 5-9}

Using the data in the table and service level of \(87.5 \%\) related to an FOS policy, find the safety stock.
\begin{tabular}{|l|l|l|l|}
\hline \multicolumn{1}{|c|}{i} & \(D_{L_{i}}\) & \(P_{\left(D_{\left.L_{i}\right)}\right)}\) & \(F_{\left(D_{\left.L_{i}\right)}\right)}\) \\
\hline 1 & 30 & 0.025 & 0.025 \\
\hline 2 & 40 & 0.1 & 0.125 \\
\hline 3 & 50 & 0.2 & 0325 \\
\hline 4 & 60 & 0.35 & 0.675 \\
\hline 5 & 70 & 0.2 & 0.875 \\
\hline 6 & 80 & 0.1 & 0.975 \\
\hline 7 & 90 & 0.025 & 1.00 \\
\hline
\end{tabular}

\section*{Solution}
\(\operatorname{Pr}\left(D_{L} \leq r\right)=87.5 \% \Rightarrow r=70\)
\(S S=r-E\left(D_{L}\right)=70-\sum_{i=1}^{7} D_{L_{i}} P_{\left(D_{L_{i}}\right)}=70-60=10\)
If the service level is not found in the table the greater service level in the table should be chosen.

\section*{Example 5-10}

If the shortage probability in an FOS policy is \(30 \%\) and the probability of the demand during the lead time \(\left(D_{L}\right)\) is as shown in the following table, find the safety stock.
\begin{tabular}{|l|l|l|}
\hline \(\mathrm{D}_{\mathrm{L}}\) & probability & Cum. Probability \\
\hline 80 & 0.3 & 0.3 \\
\hline 85 & 0.2 & 0.5 \\
\hline 90 & 0.05 & 0.55 \\
\hline 95 & 0.2 & 0.75 \\
\hline 100 & 0.15 & 0.9 \\
\hline 105 & 0.1 & 1 \\
\hline
\end{tabular}

\section*{Solution}
\(S . S=r-E\left(D_{L}\right)\)
\(E\left(D_{L}\right)=(80)(0.3)+\cdots+(105)(0.1)=90\)
Shortage probability \(=0.3 \Rightarrow p=0.7\)
\(\operatorname{Pr}\left(D_{L} \leq r\right)=0.7 \Rightarrow r=95\)
\[
r=E\left(D_{L}\right)+S S \Rightarrow S S=5
\]

\section*{Example 5-11}
(Asadzade et al ,2006, page 245)
The daily demand for a product is deterministic and equals 20 units. The policy used is FOS and the probability distribution of the lead time follows the data given in the following table. Find the safety stock for a service level of 0.85
\begin{tabular}{|l|r|r|r|r|r|r|}
\hline \(\mathrm{T}_{\mathrm{L}}\) or L & 1 & 2 & 3 & 4 & 5 & 6 \\
\hline Probability & 0.05 & 0.1 & 0.15 & 0.35 & 0.25 & 0.1 \\
\hline
\end{tabular}

\section*{Solution}

Since \(D_{L}=D \times \mathrm{T}_{\mathrm{L}}\) then we have the following probabilities:
\begin{tabular}{|l|l|l|}
\hline\(D_{L}=\mathrm{D} \times \mathrm{L}\) & probability & \begin{tabular}{l} 
Cumulative \\
probability
\end{tabular} \\
\hline 20 & 0.1 & 0.1 \\
\hline 40 & 0.25 & 0.35 \\
\hline 60 & 0.35 & 0.7 \\
\hline 80 & 0.15 & 0.85 \\
\hline 100 & 0.1 & 0.95 \\
\hline 120 & 0.05 & 1 \\
\hline
\end{tabular}
\[
p=\operatorname{Pr}\left(D_{L} \leq r\right)=0.85 \Rightarrow r=80 \text {. That is whenever the }
\] inventory level reaches 80 units an order is placed.
\[
\begin{aligned}
& S S=r-E\left(D_{L}\right) \\
& E\left(D_{L}\right)=20 \times 0.1+\cdots+120 \times 0.05=61 \\
& \quad \Rightarrow S S=80-61=19
\end{aligned}
\]

\section*{Example 5-12}

The demand during the lead time in a FOS policy is uniformly distributed over[0100], the order quantity is 40 units, the average demand is 400 units per year and the service level is \(90 \%\). Find SS.
Solution
\(F_{D_{L}}(x)=\operatorname{Pr}\left(D_{L} \leq x\right)=\left\{\begin{array}{cc}\frac{x-0}{100-0} & 0 \leq x \leq 100 \\ 0 & \text { otherwise }\end{array}\right.\)
\[
\begin{aligned}
& \operatorname{Pr}\left(D_{L} \leq r\right)=0.9 \Rightarrow \frac{r}{100}=0.9 \Rightarrow r=90 \\
& \quad E\left(D_{L}\right)=\frac{0+100}{2}=50, r=E\left(D_{L}\right)+S . S \Rightarrow S . S=40
\end{aligned}
\]

\section*{5－4－4 Reorder point and safety stock for normally distributed \(D_{L}\) in FOS Policy}

If \(D_{L}\) ，the demand during the lead time in a FOS policy，is normally distributed with mean and standard deviation \(\mu_{D_{L}}\) \＆ \(\sigma_{D_{L}}\) then
\(p=\operatorname{Pr}\left(D_{L} \leq r\right)\) or \(\operatorname{Pr}\left(D_{L}>r\right)=1-\mathrm{p} \Rightarrow \operatorname{Pr}\left(Z>\frac{r-\mu_{D_{L}}}{\sigma_{D_{L}}}\right)=1-\mathrm{p} \Rightarrow \frac{r-\mu_{D_{L}}}{\sigma_{D_{L}}}=\mathrm{Z}_{1 \mathrm{p}}=\mathrm{k}\).
\(r=E\left(D_{L}\right)+Z_{1-P} \sigma_{D_{L}} \quad \mathbf{D}_{\mathbf{L}}\) نرما：normal
Since \(r=E\left(D_{L}\right)+S S\) then if \(D_{L}\) is normally distrusted ：
\[
\begin{equation*}
\mathrm{SS}=\mathrm{Z}_{1-\mathrm{P}} \sigma_{\mathrm{D}_{\mathrm{L}}} \tag{5-22}
\end{equation*}
\]
norminv（ \(p\) ）gives the values of \(Z_{1-P}\) in MATLAB．Also the following table gives the value of \(Z_{1-P}\) for some values of service level \(p\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline \[

\end{tabular}

In what follows we would like to deal with the cases in FOS policy where the service level p and the distribution of demand and／or that of \(\mathrm{T}_{\mathrm{L}}\) are known to determine reorder point and safety stock．

\section*{5．4．5 Determining safety stock and reorder point in（r，Q） system when demand and／or lead time is probabilistic}

The aim of this section is to distinguish the cases in which the demand per unit time or the lead time or both are probabilistic in
order to calculate their mean and standard deviation and then to calculate the reorder point and safety stock in an FOS system.

Again it is reminded not to use demand per unit time(D) whose mean and variance are \(\mu_{D}=E(D) \& \operatorname{Var}(D)=\sigma_{D}^{2}\), instead of the demand during the lead time ( \(D_{L}\) ) whose mean and variance are denoted by \(E\left(D_{L}\right) \& \operatorname{Var}\left(D_{L}\right)\).

To calculate the mean and variance of \(D_{L}\), assuming D and \(\mathrm{T}_{\mathrm{L}}\) are independent, consider the 4 following cases:

\section*{5-4-5-1: Case 1: Demand and lead time ( \(D \& L=T_{L}\) ) probabilistic and independent}

Suppose the demand (per year, month...) D is a random variable with \(E(D)=\mu_{D} \& \operatorname{Var}(D)=\sigma_{D}^{2}\) and the lead time \(\left(\mathrm{L}=\mathrm{T}_{\mathrm{L}}\right)\) is also probabilistic with mean \(\mu_{L} \&\) variance \(\operatorname{Var}(L)=\sigma_{L}^{2}\). If these 2 variables are independent, then
\[
\begin{equation*}
E\left(D_{L}\right)=\mu_{D} \mu_{L} \tag{5-24-1}
\end{equation*}
\]

And according to theorem 1-5:
\[
\begin{equation*}
\sigma_{D_{L}}=\sqrt{\mu_{D}^{2} \sigma_{L}^{2}+\mu_{L} \sigma_{D}^{2}} . \tag{5-24-2}
\end{equation*}
\]

In the special case in which the demand during the lead time \(\left(D_{L}\right)\) is normally distributed, given service level (p):
\[
\begin{aligned}
& p=\operatorname{Pr}\left(D_{L} \leq r\right)=\operatorname{Pr}\left(Z \leq \frac{r-\mu_{D} \mu_{L}}{\sigma_{D_{L}}}\right), \\
& \text { Since } \frac{r-\mu_{D} \mu_{L}}{\sigma_{D_{L}}}= \\
& \quad Z_{1-p} \text { then } \\
& \quad r=\mu_{D} \mu_{L}+Z_{1-p} \sigma_{D_{L}} \quad(5-25-1) \\
& \\
& \quad S S=r-\mu_{D} \mu_{L}=Z_{1-p} \sigma_{D_{L}} \quad(5-25-2)
\end{aligned}
\]

Where \(Z_{1-p}\) is a number related to standard normal distribution with probability greater than 1-p: \(\operatorname{Pr}\left(\mathrm{Z}>Z_{1-p}\right)=1-p\).

\section*{Example 5-13}

The annual demand for a product has a mean of 3600 tons and a standard deviation of 30 tons. The lead time is normally distributed with mean 15 days and standard deviation 1 day. If there are 360 working days in a year, what is the mean and standard deviation of the demand during the lead time?

\section*{Solution}

The mean of the lead time is \(\frac{15}{360}\) in year and the standard deviation is \(\frac{1}{360} \mathrm{yr}\); then
\[
\begin{aligned}
& \quad E\left(D_{L}\right)=\mu_{D} \mu_{L}=3600 \times \frac{15}{360}=150 \\
& \sigma_{D_{L}}=\sqrt{\mu_{D}^{2} \sigma_{L}^{2}+\mu_{L} \sigma_{D}^{2}}=\sqrt{(3600)^{2} *\left(\frac{1}{360}\right)^{2}+\left(\frac{15}{360}\right) *(30)^{2}}=11.73 \\
& \text { End of example }
\end{aligned}
\]

Note that since in the unit conversion of some parameters such as \(\sigma_{D_{L}}\) we could write;
\[
\begin{aligned}
& \sigma_{D_{L}}=\sqrt{(3600)^{2} *\left(\frac{1}{360}\right)^{2}+\left(\frac{15}{360}\right) *(30)^{2}}= \\
& \sqrt{\left(\frac{3600}{360}\right)^{2} \times(1)^{2}+(15) \times\left(\frac{30}{\sqrt{360}}\right)^{2}}
\end{aligned}
\]

Then the following point has to be mentioned.

\section*{5-4-5-1-1 Some points on the unit conversion of demand's variance and standard deviation}

When the variance of demand i.e. \(\operatorname{Var}(D)\) is expressed in \(\left(\frac{\text { units }^{2}}{\text { unit time }}\right)\) and \(\sigma_{D}\) in ( \(\left.\frac{\text { unit }}{\sqrt{\text { unit time }}}\right)\) then to convert the standard deviation of monthly demand to that of yearly demand, multiply it by \(\sqrt{12}\), because:
\(\sigma_{D}=\mathrm{a}\left(\right.\) in: \(\left.\frac{\text { units }}{\sqrt{\text { month }}}\right)=\mathrm{a} \frac{\text { units }}{\sqrt{\text { year } \times \frac{1}{12}}}=\sqrt{12} \times \mathrm{a}\left(\mathrm{in}: \frac{\text { units }}{\sqrt{\text { year }}}\right)\).
e.g. \(\sigma_{\mathrm{D}}=10\) units/month is equivalent to \(\sigma_{\mathrm{D}}=10 \sqrt{12}\) units per year.

To covert the variance of monthly demand to that of yearly demand, multiply it by 12 ; also to convert the variance of daily demand to that of yearly demand, multiply it by \(\mathrm{N}=\) no. of working days in a year. To covert the standard deviation of daily demand to that of annual demand, multiply it by \(\sqrt{\mathrm{N}}\).
To covert the standard deviation of annual demand to that of daily or monthly demand, divide it by \(\sqrt{\mathrm{N}}\) or \(\sqrt{12}\) respectively.
For calculating \(\sigma_{D_{L}}\), it is easier to state the mean and standard deviation of the lead time \((\mathrm{L})\) in terms of the time units given for the demand D. For example if we have annual demand and the mean and standard deviation of L is given in units/(day or month); divide the mean and the standard deviation by 12 or N .

\section*{Example 5-14}

A warehouse uses an FOS policy with the service level \(\mathrm{p}=\% 97\). The monthly demand is estimated to be 300 tons on average with a standard deviation of 8.67. The unit price per ton of the product is \(\$ 8000\), the ordering cost is \(\$ 3000\) per order, the insurance + tax money blockade \(+\ldots\) is calculated in interest rate of \(20 \%\). The lead time is normally distributed with mean 15 days and standard deviation of 1 day. D and \(\mathrm{T}_{\mathrm{L}}\) are independent and \(\mathrm{D}_{\mathrm{L}}\) is normally distributed Find a)the reorder point and SS b)the quantity for each order. There are 360 working days and 1230 -day month in a year.

\section*{Solution}
\[
\begin{aligned}
& S S=Z_{1-p} \sigma_{D_{L}}=Z_{0.03} \sigma_{D_{L}} \\
& \sigma_{D_{L}}=\sqrt{\mu_{D}^{2} \sigma_{L}^{2}+\mu_{L} \sigma_{D}^{2}}==\sqrt{300^{2} *\left(\frac{1}{30}\right)^{2}+\left(\frac{15}{30}\right) *(8.66)^{2}}=11.73 \\
& \text { Based on Section 5-4-5-1-1 we have the following unit }
\end{aligned}
\] conversion:
\[
\begin{aligned}
& \sigma_{D}=8.67 \times \sqrt{12}=30 \text { tons per yr } \\
& \mu_{D}=300 \times 12=3600 \text { tons } / \mathrm{yr} .
\end{aligned}
\]

Since according to theorem 5-1
\[
\begin{aligned}
& \sigma_{D_{L}}=\sqrt{\mu_{D}^{2} \sigma_{L}^{2}+\mu_{L} \sigma_{D}^{2}} \\
& \quad \sigma_{D_{L}}=\sqrt{(300 \times 12)^{2} *\left(\frac{1}{360}\right)^{2}+\left(\frac{15}{360}\right) *(30)^{2}}=11.73 \\
& E\left(D_{L}\right)=E(D) E\left(T_{L}\right)=3600 \times \frac{15}{360}=150
\end{aligned}
\]

The variable \(D_{L}\) here is the product of 2 normally distributed variables i.e. D and \(T_{L}\). If the distribution of \(D_{L}\) be approximated with \(\mathrm{D}_{\mathrm{L}} \sim \mathrm{N}(150,11.73)\) then:
\(S . S=Z_{0.03} \times \sigma_{D_{L}}=1.88 \times 11.73 \cong 22\) \(r=E\left(D_{L}\right)+S S=172\)

Furthermore the following value is proposed for the order quantity:
\(Q=\sqrt{\frac{2 \mu_{D} \times C_{O}}{C_{h}}}=\sqrt{\frac{2 \times 3600 \times 3000}{0.2 \times 800}}=367\)
That is whenever the inventory reaches \(\mathrm{r}=172\), place an order of quantity 372 units.

\section*{5-4-5-2 Case 2: Demand(D) Deterministic but lead time ( \(\mathrm{L}=\mathrm{T}_{\mathrm{L}}\) )} probabilistic
In this case:
\[
\begin{aligned}
& \quad \mu_{D}=E(D)=D \quad, \sigma_{D}=0 \\
& D_{L}=D T_{L} \quad E\left(D_{L}\right)=\mu_{D} \times \mu_{L}=D \mu_{L} \quad(5-26) \\
& \sigma_{D_{L}}=\sqrt{\mu_{D}^{2} \sigma_{L}^{2}+\mu_{L} \sigma_{D}^{2}}=\sqrt{D^{2} \sigma_{L}^{2}+\mu_{L} \times 0} \Rightarrow \\
& \sigma_{D_{L}}=D \sigma_{L}
\end{aligned}
\]

In the special case where \(T_{L}\) has the normal distribution \(N\left(\mu_{L}, \sigma_{L}\right)\)

We have:
\(D_{L}=D \times T_{L} \sim N\left(D \mu_{L}, D \sigma_{L}\right)\).
Calculation of reorder point:
\(r=E\left(D_{L}\right)+S S\)
\(Z_{1-P}=\frac{r-E\left(D_{L}\right)}{\sigma_{D_{L}}}\)
\(r=E\left(D_{L}\right)+Z_{1-p} \times \sigma_{D_{L}}\)
Then
\[
r=D \mu_{L}+Z_{1-P} \times D \times \sigma_{L}(5-28)
\]
and
\[
\begin{equation*}
S S=r-E\left(D_{L}\right)=Z_{1-P} D \sigma_{L} \tag{5-29}
\end{equation*}
\]

\section*{Example 5-15}

A shop uses an FOS policy with the service level \(\mathrm{p}=\% 97.5\).
The annual dement for a product is 1000 units and the lead time is normally distributed mean 1 month and standard deviation 0.2 month. Find reorder point and the required safety stock.

\section*{Solution}
\(T_{L} \sim N\left(\mu_{L}=1\right.\) month,\(\sigma_{L}=0.2\) month \()\)
\(\sigma_{D_{L}}=D \sigma_{L}=1000 \times \frac{0.2}{12}=16.67 \quad\) or \(=\frac{1000}{12} \times \frac{2}{10}=16.67\)
\(S S=Z_{1-p} \sigma_{D_{L}}=Z_{0.025} \times 16.67, Z_{0.025}=\operatorname{norminv}(1-0.025)=1.96\)
\(S S=1.96 \times 16.67=32.66\)
\(r=E\left(D_{L}\right)+\mathrm{SS}=r=1000 \times \frac{1}{12}+32.66=116\)

\section*{5-4-5-3 Case 3: Demand(D) probabilistic but lead time deterministic}

If the (monthly, annual,...)demand is a random variable with mean \(\mu_{D}\) and standard deviation \(\sigma_{D}\) but the lead time is either fixed or has a small variations compared to its mean then \(\mu_{L}=E\left(T_{L}\right)=T_{L} \quad, \quad \sigma_{L} \cong 0\) \(D_{L}=D T_{L}\)
\[
\begin{gather*}
\mathrm{E}\left(D_{L}\right)=T_{L} \mu_{D} \quad(5-30) \\
\sigma_{D_{L}}=\sqrt{\mu_{D}^{2} \sigma_{L}^{2}+\mu_{L} \sigma_{D}^{2}}=\sqrt{\mu_{D}^{2} \times 0+T_{L} \sigma_{D}^{2}} \Rightarrow  \tag{5-31}\\
\sigma_{D_{L}}=\sigma_{D} \sqrt{T_{L}}
\end{gather*}
\]

In special case in which \(\mathrm{D} \sim N\left(\mu_{D}, \sigma_{D}\right)\) and \(T_{L}\) is fixed then

\section*{Chapter 5 Inventory control under uncertainty 268}
\[
\begin{gather*}
D_{L} \sim N\left(\mu_{D_{L}}=T_{L} \mu_{D}, \sigma_{D_{L}}=\sigma_{D} \sqrt{T_{L}}\right) \\
r=E\left(D_{L}\right)+\mathrm{SS} \\
\mathrm{SS}=Z_{1-P} \sigma_{D} \sqrt{T_{L}} \tag{5-32}
\end{gather*}
\]

\section*{Example 5-16}

A distributer uses FOS policy with a service level of \(p=97.5 \%\) for \(a\) product whose annual demand is normally distributed with mean 8000 and standard deviation of 1000 . The lead time is approximately one half of a month. Find the safety stock and the reorder point.

\section*{Solution}

The problem satisfies the conditions Eq. 5-32 i.e.
\[
\begin{aligned}
& \mathrm{SS}=Z_{1-P} \sigma_{D} \sqrt{T_{L}}=Z_{1-0.975} \times 1000 \sqrt{0.5 / 12} \\
& \quad=1.96 \times 204.12=400 \\
& \quad r=E\left(D_{L}\right)+\mathrm{SS} \quad E\left(D_{L}\right)=E(D) E\left(T_{L}\right)=\frac{8000}{12} \times \frac{1}{2}=333 \\
& r=333+400=733
\end{aligned}
\]

\section*{5-4-5-4 Case 4: Both demand and lead time deterministic}

When both D and \(\mathrm{T}_{\mathrm{L}}\) are deterministic
\(E\left(D_{L}\right)=E\left(D T_{L}\right)=D T_{L} \quad \sigma_{D_{L}}=0\)
\(r=E\left(D_{L}\right)+\mathrm{SS}\)
In chapter 2 we saw if both D and \(\mathrm{T}_{\mathrm{L}}\) are fixed:
\(r=\mathrm{ROP}=D T_{L}\), then \(\mathrm{SS}=0\).
In fact we have a classic EOQ model

\section*{5-4-6 On Lost sale and stockout in FOS systems}

In continuous review system, shortage occurs when the demand during the lead time exceeds the reorder point. Given a service level of p in a continuous review system, the shortage probability equals \(\operatorname{Pr}\left(D_{L}>r\right)=1-p\). In fact in every n cycles, the ratio of "number of cycles encountered with stockout" to the total number of the cycles i.e. \(n\), equal to \(1-\mathrm{p}\); e.g. if \(\mathrm{p}=0.88\). On the average there are 12 cycles (out of 100 cycles) in which a lost sale or shortage occurs.

Let \(b(x)\) denote the shortage function in each cycle of our FOS system then:
\[
\mathrm{b}(\mathrm{x})= \begin{cases}0 & x \leq r  \tag{5-33}\\ x-r & x>r\end{cases}
\]
where
\(\mathrm{x}=\) the demand during the lead time

\section*{The average of shortage function:}

If the demand is continuous with density function of \(f_{D_{L}}(x)\) then
\[
E[b(x)]=\int_{-\infty}^{\infty} b(x) f_{D_{L}}(x) d x=\int_{-\infty}^{r} 0 f_{D_{L}}(x) d x+\int_{r}^{\infty}(x-r) f_{D_{L}}(x) d x
\]

Since this value depends on r , The average of the shortage function is denoted by \(\bar{b}(r)\), then
\[
\begin{equation*}
\bar{b}(r)=\int_{r}^{\infty}(x-r) f_{D_{L}}(x) d x \tag{5-26}
\end{equation*}
\]

Where
\(f_{D_{L}}(x)\) is the pdf of the demand during the lead time
\(\bar{b}(r)\) is the average shortage during each cycle(b stands for bereft). if the demand is discrete with probability function of \(p_{D_{L}}(x)\) then
\[
\bar{b}(r)=\sum_{x>r}(x-r) p_{D_{L}}(x)
\]

If the order quantity in each cycle is Q and the annual demand for the product I is D then annual average shortage denoted by \(\bar{B}(r)\) is:

\section*{Annual average shortage:}
\[
\overline{\mathrm{B}}(\mathrm{r})=\frac{\mathrm{D}}{\mathrm{Q}} \overline{\mathrm{~b}}(\mathrm{r})=\frac{\overline{\mathrm{b}}(\mathrm{r})}{\mathrm{T}}=\mathrm{m} \overline{\mathrm{~b}}(\mathrm{r}),(5-28)
\]
where \(m=\frac{1}{T}\) is the number orders per year.
Therefore as much as \(\frac{\bar{B}(r)}{D} \times 100\) percent of the annual demand the inventory system encounters lost sale or shortage. If p is given as the service level, the shortage probability is 1-p and according the concept of probability, the average of the annual number of the cycles in which shortage occurs is:
\[
N_{b}=\frac{D}{Q}(1-\mathrm{p})=\mathrm{m}(1-\mathrm{p}) \quad(5-29)
\]

Then on the average every \(T_{b}=\frac{1}{N_{b}}\) years a shortage occurs.
The above results are summarized in the following table:
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 270 \\
\hline
\end{tabular}
\begin{tabular}{|l|c|c|c|}
\hline \begin{tabular}{l} 
Type of \\
demand \\
distribution
\end{tabular} & \(E\left(D_{L}>r\right)\llcorner\bar{b}(r)\) & & \(\left(N_{b}\right)\) \\
\hline continuous & \begin{tabular}{l}

\end{tabular} & \((5-28)\) & \((5-29)\) \\
\hline
\end{tabular}

Fig. 5-9 The time between 2 consecutive shortages in an FOS system
Figure 5-9 illustrates the time between two consecutive shortages. The mean of this time, denoted by \(T_{b}\), is derivable from:
\[
\begin{equation*}
T_{b}=\frac{1}{N_{b}}=\frac{Q}{\mathrm{D}(1-\mathrm{p})} \tag{5-30}
\end{equation*}
\]

There fore the shortage probability equals:
\[
\begin{equation*}
T_{b}=\frac{1}{N_{b}}=\frac{Q}{\mathrm{D}(1-\mathrm{p})} \tag{5-31}
\end{equation*}
\]
therefore
\[
\begin{equation*}
\text { shotage probability }{ }^{\prime}=1-\mathrm{p}=\frac{N_{b}}{\frac{D}{Q}} \tag{5-31}
\end{equation*}
\]

The service level i.e. the probability of the lack of shortage is estimated from
\[
\begin{equation*}
\hat{p}=1-\frac{Q N_{b}}{\mathrm{D}} \tag{5-32}
\end{equation*}
\]

Note that since \(\mathrm{Q}=\sqrt{\frac{2 \mu_{D} C_{O}}{C_{h}}}\) then:
-An increase in ordering cost \(\left(C_{o}\right)\) will increase Q and will decrease average annual shortage in FOS pliocy i.e. \(\overline{\mathrm{B}}(\mathrm{r})\)
--A decrease in holding cost \(\left(C_{h}\right)\) will decrease Q and will increase \(\overline{\mathrm{B}}(\mathrm{r})\).
What will be the effect of an increase in demand on \(\overline{\mathrm{B}}(\mathrm{r})\).?

\section*{Example 5-17}

An FOS inventory system reports 2 shortages per year on the average. The quantity per order is 800 and the average annual demand is 8000 . Estimate the service level?

\section*{Solution}
\[
\hat{\mathrm{p}}=1-\frac{Q N_{b}}{\mathrm{E}(\mathrm{D})}=1-\frac{800 \times 2}{8000}=0.80 \text { End of example }
\]

\section*{Example 5-18}

The demand during the lead time in an FOS system is uniformly distributed over [0 100]. If the survive level is \(90 \%\) and order of 40 units are placed, what is the ratio of " annual average shortage " to " annual demand" ?

\section*{Solution}
\[
\begin{aligned}
& \frac{\bar{B}(r)}{D}=? \\
& \bar{B}(r)=\frac{D}{Q} \bar{b}(r), \quad \bar{b}(r)=\int_{r}^{\infty}(x-r) f_{D_{L}}(x) d x \\
& \mathrm{f}(\mathrm{x})=\frac{1}{100} \quad 0 \leq \mathrm{x} \leq 1 \cdots \quad \mathrm{~F}(\mathrm{x})=\frac{\mathrm{r}-0}{100-0} \\
& \operatorname{Pr}\left(D_{L} \leq r\right)=p=0.9 \quad \frac{r-0}{100-0}=0.9 \quad \Rightarrow r=90 \\
& \quad \bar{b}(r)=\int_{90}^{100}(x-90) \frac{1}{100} d x=0.5 \\
& \frac{\bar{B}(r)}{D}=\frac{\bar{b}(r)}{Q}=\frac{0.5}{40}=1.25 \%
\end{aligned}
\]

\section*{Example 5-19}

The demand during the lead time in an FOS system is according the data in the following table, If the safety stock is three tons. What is the average shortage per cycle?
\begin{tabular}{|c|l|l|l|l|l|l|l|l|l|l|l|}
\hline \(\mathrm{D}_{\mathrm{L}}\) (ton) & 6 & 7 & 8 & 9 & 10 & 11 & 12 & 13 & 14 & 15 & 16 \\
\hline Probability(\%) & 5 & 5 & 5 & 5 & 2 & 2 & 2 & 5 & 5 & 5 & 5 \\
\hline
\end{tabular}

\section*{Solution}
\[
\begin{gathered}
\bar{b}(r)=\sum_{x>r}(x-r) p_{X}(x) \quad, r=E\left(D_{L}\right)+S S \\
E\left(D_{L}\right)=6 \times 0.05+\ldots+16 \times 0.05=11 r=11+3=14 \text { tons } \Rightarrow \\
\bar{b}(r)=\sum_{x>14}(x-14) P_{X}(x)=(15-14)(0.05)+(16-14)(0.05)=0.15
\end{gathered}
\]

5-4-6-1 Calculation of average shortage in FOS systems when \(D_{L}\) is normally distributed using normal loss integral

If the demand during the lead time \(\left(\mathrm{D}_{\mathrm{L}}\right)\) is normally distributed with mean \(\mu_{D_{L}}\) and standard deviation \(\sigma_{D_{L}}\) and density function \(f_{D_{L}}(x)=\frac{1}{\sigma_{D_{L}} \sqrt{2 \pi}} e^{-\frac{\left(x-\mu_{D_{L}}\right)^{2}}{2 \sigma_{D_{L}}}}\) then the average shortage per cycle which is derived from
\[
\bar{b}(r)=\int_{x=r}^{\infty}(x-r) \frac{1}{\sigma_{D_{L}} \sqrt{2 \pi}} e^{-\frac{\left(x-\mu_{D_{L}}\right)^{2}}{2 \sigma_{D_{L}}}} d x
\]

Is calculabled from(see Sec. 1.5.1):
\[
\bar{b}(r)=\sigma_{D_{L}} G_{U}(k) \quad k=\frac{r-\mu_{D_{L}}}{\sigma_{D_{L}}} \quad(5-33)
\]
where
\[
k=Z_{1-P}=\frac{r-\mu_{D_{L}}}{\sigma_{D_{L}}} .
\]

The function \(G_{U}(k)\) which is called unit loss normal integral is a function of \(\mathrm{k}=\mathrm{Z}_{1-\mathrm{P}}\), known some times as safety coefficient; the more this coefficient the less \(G_{U}(k)\) and the less the shortage. The values of this function could be calculated using MATLB command \(\exp \left(-\mathrm{k}^{\wedge} 2 / 2\right) / \operatorname{sqrt}(2 * \mathrm{pi})-\mathrm{k} *(1-\operatorname{normcdf}(\mathrm{k}))\); some its values are given below:
\begin{tabular}{|l|l|l|l|}
\hline \multicolumn{4}{|c|}{ Some values of \(G_{U}(k)\)} \\
\hline \(\mathrm{p}(\%)\) & \(1-\mathrm{p}\) & k & \(G_{U}(k)\) \\
\hline 99.9 & 0.001 & 3.45 & 0.00007127 \\
\hline 99 & 0.01 & 2.33 & 0.003352 \\
\hline 97.5 & 0.025 & 1.96 & 0.009445 \\
\hline 95 & 0.05 & 1.64 & 0.02114 \\
\hline 0.93 & 0.07 & 1.48 & 0.03070 \\
\hline 92.5 & 0.075 & 1.44 & 0.03356 \\
\hline 90 & 0.1 & 1.28 & 0.04750 \\
\hline
\end{tabular}

\section*{Example 5-20}

In an FOS system, the average demand is 200 units, orders are placed with quantity \(\mathrm{Q}=30\) units. The consumption during
the lead time is normally distributed :
\[
\mathrm{D}_{\mathrm{L}} \sim \mathrm{~N}\left(\mu_{\mathrm{D}_{\mathrm{L}}}=58.3, \sigma_{\mathrm{D}_{\mathrm{L}}}=13.1\right) . \text { Find } \overline{\mathrm{b}}(\mathrm{r}), \mathrm{ROP}, \mathrm{SS}, \mathrm{~T}_{\mathrm{b}} .
\]

\section*{Solution}
\[
\mathrm{T}_{\mathrm{b}}=\frac{\mathrm{Q}}{\mathrm{D}(1-\mathrm{p})}=\frac{30}{200(1-0 / 925)}=2 \mathrm{yr}
\]

This means that on average every 2 years the systems encounter a shortage and the average number of shortages is
\[
\begin{aligned}
& \mathrm{N}_{\mathrm{b}}=\frac{1}{\mathrm{~T}_{\mathrm{b}}}=\frac{1}{2} \mathrm{yr} . \\
& \mathrm{ROP}=\mathrm{r}=\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)+\mathrm{Z}_{1-\mathrm{p}} \sigma_{\mathrm{D}_{\mathrm{L}}}= \\
& 58.3+\mathrm{z}_{(1-0 / 925)} \times 13.1=58.3+1.44 \times 13.1=77.16 \\
& \mathrm{SS}=1.44 \times 13.1=18.9 \\
& \text { Since } \mathrm{D}_{\mathrm{L}} \text { is normally distributed: }
\end{aligned}
\]
\[
\begin{aligned}
& \bar{b}(r)=\sigma_{D_{L}} \times G_{U}(k) \quad k=\frac{r-\mu_{D_{L}}}{\sigma_{D_{L}}}=1.48 \\
& \mathrm{k}=1.48 ; \exp \left(-\mathrm{k}^{\wedge} 2 / 2\right) / \operatorname{sqrt}\left(2^{*} \mathrm{pi}\right)-\mathrm{k} *(1-\operatorname{normcdf}(\mathrm{k})) \Rightarrow 0.0307 \\
& \overline{\mathrm{~b}}(\mathrm{r})=(13.1)(0.0307)=0.44
\end{aligned}
\]

\section*{Example 5-21}

In An FOS system, the demand during the lead time is normally distributed with mean 58.3 and standard deviation 13.1. Assuming a service level of \(90 \%\), find the average shortage per cycle. What is the reorder point?

\section*{Solution}
\[
\begin{aligned}
& k=Z_{1-p}=Z_{0.1}=\operatorname{norminv}(1-.1)=1,2816 \\
& \bar{b}(r)=\sigma_{D_{L}} G_{U}(k)=13.1 * G_{U}(1.28)=13.1 \times 0.04750=0.62 \\
& \quad r=E\left(D_{L}\right)+k \sigma_{D_{L}}=58.3+(1.28)(13.1)=75.07
\end{aligned}
\]

\section*{5-4-7 Average inventory in FOS system}

The inventory average ( \(\overline{\mathrm{I}}\) ) and the mean of holding cost in continuous review systems are as follows:
\[
\begin{equation*}
\bar{I}=\frac{Q}{2}+S . S \tag{5-34}
\end{equation*}
\]
averagge hoding cost \(=\bar{I} \times C_{h}\)

\section*{Example 5-22}

In an FOS inventory model, as well as the data in the following table, we know that the average demand is 4000 per year, the order size is fixed, the annual unit holding cost is \(\$ 10\), the service level is \(90 \%\) and the ordering cost is \(\$ 50\). Find the optimal order quantity, the reorder point, the safety stock holding cost, the average inventory and its annual holding cost

\section*{Solution}
\[
\begin{aligned}
& \begin{array}{|l|l|l|l|}
\hline \mathrm{i} & D_{L_{i}}=x_{i} & p_{i} & \text { Cumulative probability } \\
\hline 1 & 11 & 0.10 & 0.1 \\
\hline 2 & 13 & 0.20 & 0.3 \\
\hline 3 & 15 & 0.40 & 0.7 \\
\hline 4 & 17 & 0.20 & 0.9 \\
\hline 5 & 19 & 0.10 & 1 \\
\hline
\end{array} \\
& \mathrm{Q}^{*}=\sqrt{\frac{2 \mathrm{C}_{0} \mathrm{E}(\mathrm{D})}{\mathrm{C}_{\mathrm{h}}}}=\sqrt{\frac{2 \times 50 \times 4000}{10}}=200 \\
& \mathrm{Pr}\left(\mathrm{D}_{\mathrm{L}} \leq \mathrm{r}\right)=0.9 \Rightarrow \mathrm{ROP}=\mathrm{r}=17 \\
& \mathrm{SS}=\mathrm{r}-\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)
\end{aligned} \quad \begin{aligned}
& \mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)=\sum_{\mathrm{i}=1}^{5} \mathrm{x}_{\mathrm{i}} \mathrm{p}_{\mathrm{i}}=11 \times 0.1+\ldots+19 \times 0.1=15 \\
& \mathrm{SS}=\mathrm{r}-\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)=17-15=2 \\
& \overline{\mathrm{I}}=\frac{\mathrm{Q}^{*}}{2}+\mathrm{SS}=\frac{200}{2}+2=102 \\
& \mathrm{SS} \text { annual holding cost }=\mathrm{SS} \times \mathrm{SS} \times C_{h}=2 \times 10=20 \\
& \text { average annual holding cost }=10 \times \bar{I}=1020 \mathrm{D}
\end{aligned}
\]
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 276 \\
\hline
\end{tabular}

\section*{5-4-8 Other ways for determining reorder point in FOS systems}

To determine the reorder point, in an FOS inventory model where demand ( D ) and/or the lead time \(\left(\mathrm{T}_{\mathrm{L}}\right)\) are probabilistic, as well as
i-using Eq. 5-19 i.e. \(p=\operatorname{Pr}\left(D_{L} \leq r\right)\) which uses the service level and the probability distribution of lead time consumption,
there are 2 other was as follows
ii-using average lead time and maximum annual demand \(r=\max (D) \times E\left(T_{L}\right)\)
iii- using maximum lead time and average demand
\(r=\max \left(T_{L}\right) \times E(D) . \quad(5-36)\)
In any case \(S S=r-E\left(D_{L}\right)\).
The above 3 ways are illustrated below.

\section*{Determining reorder point given the service level and lead time} consumption distribution

\section*{Example 5-23}

Given the following table of frequencies and a fixed weekly demand of 6 units, determine the safety stock of .95 (or more) service level in an FOS system.
\begin{tabular}{|l|l|l|l|l|l|}
\hline \(\mathrm{T}_{\mathrm{L}}(\) week \()\) & 4 & 5 & 6 & 7 & um \\
\hline frequency & 14 & 18 & 12 & 6 & 50 \\
\hline probability & 0.28 & 0.36 & 0.24 & 0.12 & 1 \\
\hline
\end{tabular}

\section*{Solution}
\begin{tabular}{|c|l|l|l|l|}
\hline\(D_{L}\) & 24 & 30 & 36 & 42 \\
\hline probability & 0.28 & 0.36 & 0.24 & 0.12 \\
\hline Cum. Prob & 0.28 & 0.64 & 0.88 & 1 \\
\hline
\end{tabular}
\[
\begin{aligned}
& \mathrm{SS}=\mathrm{r}-\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right) \\
& \mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)=0.28 \times 24+\ldots+0.12 \times 42=31.2 \\
& \operatorname{Pr}\left(\mathrm{D}_{\mathrm{L}} \leq \mathrm{r}\right)^{3} 0.95 \mathrm{Pr}=42 \\
& \mathrm{SS}=42-31.2=10.8
\end{aligned}
\]

Determining reorder point given the average consumption and the maximum of lead time

\section*{Example 5-24}

The demand for a product in an FOS model is fixed and equal to 12 per 6 -day week. The following frequencies of the lead time is also available.
\begin{tabular}{lllll}
\(\mathrm{T}_{\mathrm{L}}\) (day) & 4 & 5 & 6 & 7 \\
frequency & 14 & 18 & 12 & 6
\end{tabular}

Find the reorder point and the safety stock
i) based on the service level of at least \(95 \%\).
ii)based on the maximum of the lead time if

\section*{Solution}
i) Since the consumption during \(\mathrm{T}_{\mathrm{L}}\) is given by \(D_{L}=D \times\)
\begin{tabular}{|l|l|l|l|}
\hline\(D_{L}\) & frequency & \begin{tabular}{l} 
relative \\
frequency
\end{tabular} & \begin{tabular}{l} 
Cum. \\
frequency
\end{tabular} \\
\hline 8 & 14 & 0.28 & 0.28 \\
\hline 10 & 18 & 0.36 & 0.64 \\
\hline 12 & 12 & 0.24 & 0.88 \\
\hline 14 & 6 & 0.12 & 1 \\
\hline
\end{tabular}
\[
\operatorname{Pr}\left(D_{L} \leq r\right)=0.95 \Rightarrow r=14
\]

\section*{Chapter 5 Inventory control under uncertainty}
ii)
\(r=\max \left(T_{L}\right) \times E(D)\)
\(R O P=r=T_{L_{\text {max }}} \times D=7 \times \frac{12}{6}=14\)
\(E\left(D_{L}\right)=8 \times 0.28+\cdots+14 \times 0.12=10.4\)
\(S . S=r-E\left(D_{L}\right)=14-10.4=3.6\)

\section*{Example 5-25}

In an FOS model the lead time and the demand are independent. The following data are available. Find the safety stock based on the maximum of the lead time and the average demand.
\begin{tabular}{|l|l|l|l|l|l|l|l|l|}
\hline period & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
\hline demand & 30 & 60 & 50 & 30 & 60 & 50 & 70 & 50 \\
\hline \(\mathrm{~T}_{\mathrm{L}}\) (day) & 6 & 5 & 7 & 3 & 6 & 5 & 4 & 4 \\
\hline
\end{tabular}

\section*{Solution}
\(S S=r-E\left(D_{L}\right)=r-E(D) \times E\left(T_{L}\right), \quad \hat{E}(D)=\bar{D}=\frac{30+\ldots+50}{8}=50\)
\[
\hat{E}\left(T_{L}\right)=\frac{6+\ldots+4}{8}=5
\]
\[
r=\max \left(T_{L}\right) \times E(D)=7 \times 50=350
\]
\[
S S=350-5 \times 50=100
\]

Determining reorder point given the demand maximum and the lead time average

\section*{Example 5-26}

Solve the previous example again using \(r=\max (D) E\left(T_{L}\right)\)

\section*{Solution}
\[
S S=r-E\left(D_{L}\right) \quad r=\max (D) E\left(T_{L}\right)=70 \times 5=350
\]
\(\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)=\mathrm{E}(\mathrm{D}) \mathrm{E}\left(\mathrm{T}_{\mathrm{L}}\right)=50 \times 5=250\)
\(S S=r-E\left(D_{L}\right)=350-250=100\)

It worth mentioning that the maximum inventory in FOS model is \(\mathrm{r}+\mathrm{Q}\); e.g. in the previous example if the order quantity is 520 the maximum of the inventory would be 870 .

\section*{Example 5-27}

The frequencies of \(\mathrm{T}_{\mathrm{L}}\) in an FOS system in given below. The demand is fixed and equal to 6 per week. Find the safety stock and reorder based on maximum demand. There 6 working days in a week.
\begin{tabular}{|l|l|l|l|l|}
\hline \(\mathrm{T}_{\mathrm{L}}\) (day) & 4 & 5 & 6 & 7 \\
\hline frequency & 14 & 18 & 12 & 6 \\
\hline
\end{tabular}

\section*{Solution}
\[
\begin{aligned}
& r=\max (D) E\left(T_{L}\right), \quad \max (D)=\frac{q}{q}=1, \\
& \hat{E}\left(T_{L}\right)=\frac{4 \times 14+5 \times 18+6 \times 12+7 \times 6}{50}=\frac{260}{50}=5.2
\end{aligned}
\]
\[
r=1 \times 5.2=5.2
\]

Since the demand per day is equal to one, the lead time consumption \(\left(D_{L}\right)\) and the related frequency would be
\begin{tabular}{|c|l|l|l|l|}
\hline \(\mathrm{D}_{\mathrm{L}}\) & 4 & 5 & 6 & 7 \\
\hline frequency & 14 & 18 & 12 & 6 \\
\hline
\end{tabular}
\[
S S=r-E\left(D_{L}\right) \quad \hat{E}\left(D_{L}\right)=\frac{4 \times 14+5 \times 18+6 \times 12+7 \times 6}{50}=5.2
\]
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 280 \\
\hline
\end{tabular}

At the end of this section some useful relations used in contiguous review model are given below:
\begin{tabular}{|l|l|}
\hline \multicolumn{2}{|c|}{ Some relations related to \((\mathrm{r}, \mathrm{Q})=\mathrm{FOS}\) model } \\
\hline Desired order quantity & \(Q^{*}=\sqrt{\frac{r_{0} E(D)}{C_{h}}}\) \\
\hline \begin{tabular}{l} 
annuual average \\
shortage
\end{tabular} & \(\bar{B}(r)=D \times \frac{\bar{b}(r)}{Q^{*}}\) \\
\hline \begin{tabular}{l} 
ratio of shortage to \\
demand
\end{tabular} & \(\frac{\bar{B}(r)}{D}=\frac{1}{Q^{*}} \bar{b}(r)\) \\
\hline Average Inventory & \(\bar{I}=\frac{Q^{*}}{2}+S S\) \\
\hline \begin{tabular}{l} 
Average number of \\
shortages per year
\end{tabular} & \(N_{b}=\frac{D}{Q^{*}} \operatorname{Pr}\left(D_{L}>r\right)=\frac{D(1-p)}{Q^{*}}\) \\
\hline \begin{tabular}{l} 
Safety stock in lost \\
sale FOS
\end{tabular} & \(S S=r^{*}-E\left(D_{L}\right)+\bar{b}(r)\) \\
\hline \begin{tabular}{l} 
Safety stock in FOS-- \\
\(D_{L}\) normally \\
distributed
\end{tabular} & \(S S=Z_{1-p} \sigma_{D_{L}}=k \sigma_{D_{L}}\) \\
\hline \begin{tabular}{l} 
Average shortage per \\
period- \(D_{\mathrm{L}}\) normally \\
distributed
\end{tabular} & \(\bar{b}(r)=\sigma_{D_{L}} \times G_{U}(k)\) \\
\hline
\end{tabular}

\section*{5-5 Two-bin or max-min policy}

A special case of continuous review ( \(\mathrm{r}, \mathrm{Q}\) ) model is what is called two-bin or max-min model. In this model \(T_{L}<T\) and there are two bins either physically or virtually; one is used for supplying current demand and the other for satisfying demand during the lead time. When the first bin which is greater is depleted; an order is placed as much as the capacity of this bin. The demand during the lead time is satisfied from the small bin. When the order quantity arrives, the small bin is filled at the beginning and the rest is poured into the great bin. It is possible to use one bin with a sign on it as the reorder point( Fig5-10). An application of this policy is for the goods with low price and small lead time.

Fig. 5. 10 Two-bin inventory system
In this system whenever the inventory reaches \(r\) an order is placed with a quantity equal to Q . The size of the small bin is the average demand during the lead time as well as the safety stock i.e \(r=E\left(D_{L}\right)+S S\)
where \(E\left(D_{L}\right)\) is the consumption during the lead time and SS is the safety stock.

An advantage of this policy to the general FOS model is preventing running out of stock and saving time and money.

\section*{Shartage in inventory systems}

It is important in inventory control to determine what to do when a costumer arrives and there is no inventory temporarily. Two possible alternative are available either (Peterson, Silver, 1991, p209)
-Complete backordering i.e.to permit shortage in the system. The demands during out stock are backordered and filled as soon as new replenishment arrives.
-Complete Lost sale i.e. the demands during out stock are lost and we incur costs due to lost sale.
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 282 \\
\hline
\end{tabular}

The above two alternatives are investigated below for continuous review model (r,Q).

\subsection*{5.6Back ordering in FOS system}

In continuous review systems with back-ordering, the demands during this time are not lost but are backordered and filled as soon as adequate-sized order arrive. This policy is more common in industry \({ }^{1}\).

The order quantity ( Q ) could be calculated from Wilson formula. To determine the optimal reorder point ( \(r^{*}\) ), we assume \(r\) is not dependent on \(Q\) and distinguish two cases(Tersine, 1994 page 218):
-the stockout cost per unit is known
- the stockout cost per outage is known

\section*{5-6-1 Backordered (r Q) - Stockout cost/ unit ( \(\pi\) )known}

In (r Q) or FOS systems with back-ordering, shortage happens when X or \(\mathrm{D}_{\mathrm{L}}\) i.e. the consumption during the lead time, exceeds \(r\). In this case, when \(\pi\),i.e. the cost per each time the stockout happens, is fixed and known, the expected annual safety stock cost ( \(\mathrm{TC}_{\mathrm{ss}}\) ) is:
\(\mathrm{TC}_{\mathrm{ss}}=\) holding cost + stockout cost or:
\[
\begin{equation*}
T C_{s s}=\left(C_{h}\right)(s s)+\pi\left(\frac{D}{Q}\right) \times \bar{b}(r) \tag{5-37}
\end{equation*}
\]

Where \(\pi\) is the cost per outage, SS is the units of safety stock and \(\bar{b}(r)\) is the average stockout units (backordered units) per cycle. SS and \(\bar{b}(r)\) are calculated from:

Backordered FOS
\(s s=r-E\left(D_{L}\right)\)

\footnotetext{
\({ }^{1}\) https://www.sciencedirect.com/science/article/pii/S0377221711001354
}
\[
\begin{equation*}
\bar{b}(r)=\int_{r}^{\infty}(x-r) f_{D_{L}}(x) d x \text { or } \sum_{x>r}(x-r) p_{D_{L}}(x) \tag{5-39}
\end{equation*}
\]
where \(x\) is the demand during the lead time.
By taking derivative of Eq. 5-37 with respect to r,the following optimizing relationship results(Tersine, 1994, Proof in Johnson\&Montomeri, 1974 p59)L
\[
\frac{\partial T C_{s s}}{\partial r}=0 \Rightarrow \operatorname{Pr}\left(D_{L}>r^{*}\right)=\frac{C_{h} Q}{\pi D} \quad Q=Q_{w}=\sqrt{\frac{2 D C_{0}}{C_{h}}}
\]
or:
FOS: Back-order case ( \(\pi\) known)
\[
\begin{equation*}
F_{D_{L}}\left(r^{*}\right)=\operatorname{Pr}\left(D_{L} \leq r^{*}\right)=1-\frac{C_{h} Q}{\pi D} \tag{5-40}
\end{equation*}
\]

The above relationship is valid for both continuous and discrete probability distributions of lead time demand (Tersine, 1994 p 219 ). It is obvious if \(\frac{C_{h} Q}{\pi D}>1\) or (if \(Q=Q_{w}\) ) \(T C_{w}>\pi D\) there is no solution to the equation. this means that the cost of stockout is very low such that we prefer to have always backorder!

Notice not to mistake \(\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}>\mathrm{r}\right)\) for \(\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right) . \mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)\) is the expected demand during the lead time computable from:
\[
\begin{aligned}
& E\left(D_{L}\right)=\int_{0}^{\infty} x f_{D_{L}}(x) d x \quad \text { or } \sum_{x} x p_{D_{L}}(x) . \\
& \bar{b}(r)=E\left(D_{L}>r\right) \text { is derived from: } \\
& \bar{b}(r)=E\left(D_{L}>r\right)=\int_{r}^{\infty}(x-r) f_{D_{L}}(x) d x \quad \text { or } \\
& \bar{b}(r)=\sum_{x>r}(x-r) p_{D_{L}}(x)
\end{aligned}
\]
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 284 \\
\hline
\end{tabular}
where
\(f_{D_{L}}\) is the pdf of continuous lead time demand
\(p_{D_{L}}\) is the probability function of discrete lead time demand. In this Policy, safety stock is derived from(Winston, 1994 p 917 ):
\[
\begin{equation*}
S S=r^{*}-E\left(D_{L}\right) \tag{5-41}
\end{equation*}
\]

Example 5-28( Winston, 1994 page 917)
The annual demand is normally distributed with a mean of 1000 units and \(\sigma_{D}=40.8\). The ordering cost is \(c_{h}=10\). The backorderin
incur a cost of \(\pi=\$ 20\) per unit. Find the reorder point \(r^{*}\) and safety stock if
\(\mathrm{T}_{\mathrm{L}}\) is fixed and equal to 2 weeks
\(\mathrm{T}_{\mathrm{L}}\) is a random variable with \(E\left(T_{L}\right)=2\) weeks \(\quad \sigma_{\mathrm{T}_{\mathrm{L}}}=\frac{1}{52} \mathrm{yr}\)
In each case determine the service level.

\section*{Solution}
\[
Q^{*}=\sqrt{\frac{2(1000)(50)}{10}}=100
\]
\(\pi \mathrm{D}=20 \times 1000>\mathrm{C}_{\mathrm{h}} \mathrm{Q}^{*}=(10)(100)\); therefore the problem has a solution.
\[
\operatorname{Pr}\left(\mathrm{D}_{\mathrm{L}}>\mathrm{r}^{*}\right)=\frac{(10)(100)}{(20)(1000)}=0 / 05
\]

\section*{Part i}

Since the lead time is constant and equal to \(T_{L}=\frac{2}{52}=\frac{1}{26} \mathrm{yr}\) and the annual demand is normally distributed, therefore the lead time demand ( \(D_{L}=D \times T_{L}\) ) is also normally distributed with mean and variance :
\[
\left\{\begin{array}{l}
\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)=\mathrm{E}\left(\mathrm{D} T_{\mathrm{L}}\right)=\mathrm{E}(\mathrm{D}) \times \mathrm{E}\left(\mathrm{~T}_{\mathrm{L}}\right)=1000 \times \frac{1}{26}=38 / 46 \\
\operatorname{Var}\left(\mathrm{D}_{\mathrm{L}}\right)=\sigma_{\mathrm{D}}^{2} \mu_{\mathrm{L}}+\sigma_{L}^{2} \mu_{\mathrm{D}}^{2} \mathrm{P} \operatorname{Var}\left(\mathrm{D}_{\mathrm{L}}\right)=(40 / 8)^{2} \times \frac{1}{26}+0 \Rightarrow \sigma_{\mathrm{D}_{\mathrm{L}}}=8
\end{array}\right.
\]

Then
\[
\begin{aligned}
& \operatorname{Pr}\left(D_{L}>r^{*}\right)=\operatorname{Pr}\left[Z>\frac{r^{*}-E\left(D_{L}\right)}{\sigma_{D_{L}}}\right]=0.05 \Rightarrow \\
& \frac{\mathrm{r}^{*}-\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)}{\sigma_{\mathrm{D}_{\mathrm{L}}}}=\mathrm{z}_{0.05}=1.65 \Rightarrow r^{*}=38.46+8 \times(1.64)=51.58
\end{aligned}
\]

Whenever the inventory reaches 51 units an order of 100 units is placed. This reorder point assures a service level of \(\mathrm{p}=1-0.05=0.95\).
\[
\begin{aligned}
& \mathrm{SS}=\mathrm{r}^{*}-\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right) \stackrel{\text { normal }}{=} \mathrm{z}_{1-\mathrm{p}} \times \sigma_{\mathrm{D}_{\mathrm{L}}} \\
& \mathrm{SS}=\mathrm{z}_{1-\mathrm{p}} \times \sigma_{\mathrm{D}_{\mathrm{L}}}=(8)(1.65)=13.12 \\
& \mathrm{SS}=\mathrm{r}^{*}-\mathrm{E}\left(\mathrm{D}_{\mathrm{L}}\right)=51.58-38.46=13.12
\end{aligned}
\]

\section*{Part ii}
\[
\begin{aligned}
& \mathrm{E}\left(\mathrm{~T}_{\mathrm{L}}\right)=2 \text { weeks } \quad \sigma_{\mathrm{T}_{\mathrm{L}}}=\frac{1}{52} \mathrm{yr} \\
& \sigma_{D L}=\sqrt{\mu_{D}^{2} \sigma_{L}^{2}+\mu_{L} \sigma_{D}^{2}} \\
& \sigma_{D_{L}}=\sqrt{(1000)^{2}\left(\frac{1}{52}\right)^{2}+(40.8)^{2}\left(\frac{1}{26}\right)}=20.43 .
\end{aligned}
\]

Now suppose the lead time demand \(\left(D_{L}\right)\) is normally distributed:
\[
\begin{aligned}
& \operatorname{Pr}\left(D_{L}>r\right)=0.05 \Rightarrow \\
& r=E\left(D_{L}\right)+z_{1-p} \sigma_{D L}=E(D) E\left(T_{L}\right)+\underset{\substack{1000 \times \frac{1}{26}}}{\substack{\text { norminn(0.95) } \\
\text { I. } 1.049}}
\end{aligned} \times(20.43)
\]

Whenever the inventory reaches 72 units an order of 100 units is placed. Backordering is allowable . This reorder point assures a service level of \(\mathrm{p}=0.95\).

\section*{5-6-2 Backordered (r Q) - Stockout cost/ outage (g)known}

To determine r and Q in back-order case of continuous review model service level if the cost per outage(g) and the
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 286 \\
\hline
\end{tabular}
probability density function of lead time demand, \(f_{D_{L}}(x)\) are known, then the total cost of safety stock is(Martin\&Miller,1962 page 63):
\[
T C_{s s}=C_{h} \times S S+g\left(\frac{D}{Q}\right) \operatorname{Pr}\left(D_{L}>r\right) \quad \frac{\partial T C_{s s}}{\partial r}=\cdot \Rightarrow
\]

\section*{FOS: Backorder case , cost per outage known}
\[
\begin{aligned}
f_{D_{L}}\left(r^{*}\right) & =\frac{C_{h} Q}{g D} \\
S S & =r-E\left(D_{L}\right)
\end{aligned}
\]

To compute \(\mathrm{SS} r^{*}\) replaces r in Eq. 5-43. Q is the order quantity at the reorder point. Eq.5-42 is developed for a continuous distribution m but bfrquently integer values of inventory are possible. When the optimum reorder point lises between 2 integer values, the integer with the larger \(f_{D_{L}}\left(r^{*}\right)\) is selected(Tersine, 1994 page 219).

\section*{Example 5-29}

Weekly demand is normally distributed with mean 20units and standard deviation of 4 units. Back ordering is applied when shortage occurs. When- ever shortage occurs it incurs \$ 10. The annual holding cost is \(\$ 5\) per unit. The ordering quantity is 26units per order. Find the optimal reorder point and safety stock if the lead time is 1 week in a 52 -week year.

\section*{Solution}

The model is a continuous review with back-ordering. Since \(T_{L}\) is fixed and

D is normally distributed, then \(D_{L}=D T_{L}\) is also normally distributed with a mean and standard deviation as follows:
\[
\begin{aligned}
& E\left(D_{L}\right)=E\left(D T_{L}\right)=T_{L} E(D)=1 \times 20=20 \text { per week } \\
& \left\{\begin{array}{l}
\operatorname{Var}\left(D_{L}\right)=\sigma_{D}^{r} \mu_{L}+\sigma_{\dot{r}}^{r} \mu_{D}^{r} \Rightarrow \operatorname{Var}\left(D_{L}\right)=(4)^{2} \times 1+0 \Rightarrow \\
\sigma_{D_{L}}=4 \text { per week }
\end{array}\right.
\end{aligned}
\]

Needles to say, that we did not need to do the above calculations; because
\(D_{L}\) is the demand for one week and we have the weekly demand. The density function of the lead time in point \(r^{*}\) is:
\[
\begin{aligned}
& f_{D_{L}}\left(r^{*}\right)=\frac{C_{h} Q}{g D}=\frac{5 \times 26}{10(52 \times 20)}=0.0125 \Rightarrow \\
& \frac{1}{\sqrt{2 \pi} \sigma_{D_{L}}} e^{-\frac{1}{r}\left(\frac{r^{*}-\mu_{D_{L}}}{\sigma_{D_{L}}}\right)^{r}}=0.0125 \Rightarrow \\
& \frac{r^{*}-\mu_{D_{L}}}{\sigma_{D_{L}}}= \pm \sqrt{\operatorname{Ln} \frac{1}{2 \pi \sigma_{D_{L}}^{r} \times 0.0125^{2}}}= \pm 2.038 \\
& R O P=r^{*}=\mu_{D_{L}} \pm 2.038 \sigma_{D_{L}}=r \cdot \pm 2.038 \times 4 \cong 28.15,11.85
\end{aligned}
\]

Choosing \(r^{*}=28\) is more cautious than the other answer. Therefore whenever the inventory reaches 28 an order of size 26 is placed. \(\quad S S=r^{*}-E\left(D_{L}\right) \quad S S=28-20=8\)

Example 5-30(Tersine, 1994 page222)
Weekly demand for a product follows a Poisson distribution with mean of 5 units. The annual holding cost is \(\$ 5\). The backorder cost is \(\$ 5\) per outage. What is the optimum reorder point if \(T_{L}\) is 1 week and the order quantity is 13 units.

\section*{Solution}
\(D_{L}\) is the demand for one week and we have the distribution of weekly demand. Then \(\mathrm{D}_{\mathrm{L}}\) is poison distributed with \(\lambda=5\). \(r^{*}\) is calculated as follows:

\section*{Chapter 5 Inventory control under uncertainty 288}
\[
p_{D_{L}}\left(r^{*}\right)=\frac{C_{h} Q}{g D} \rightarrow \frac{5^{r^{*}} \times \mathrm{e}^{-5}}{\mathrm{r}^{*}!}=\frac{\frac{5}{52} \times 13}{5 \times 5}=0.05
\]

The left hand side of the equation is the probability function of poisson distribution denoted by posspdf in matLab:
poisspdf(rstar, 5) \(=0.05\)
The answer to the above equation could be found graphically. Using running the following MATLAB command, plots the a figure which is helpful to find the solution.
\(\mathrm{x}=0: 1: 10\);forI \(=1:\) length \((\mathrm{x}) ; \operatorname{pd}(\mathrm{I})=\operatorname{poisspdf}(\mathrm{x}(\mathrm{I}), 5)\);end; \(\operatorname{plot}(\mathrm{x}, \mathrm{pd})\)

This figure gives two values (near \(x \cong 2\) and \(x \cong 9\) ) for the probability 0.05.

The second answer \(r^{*}=9\) is chosen.

\section*{5-7 Lost sale case in FOS system}

As it is clear in the lost dale case all stock-outs are lost and not satisfied later. The order quantity is determined empirically or by \(Q^{*}=\sqrt{\frac{2 C_{o} E(D)}{C_{h}}}\).

To determine the optimum reorder point here, two case are distinguished i.e. lost sale cost expressed per unit or lost sale cost per outage. These two treated as follows, assuming r and Q are independent.

\section*{5-7-1 Lost sale (r Q) - Stockout cost/ unit ( \(\pi\) )known}

In continuous review systems when we have complete lost sale and the cost per unit lost \((\pi)\) is known, then \(r^{*}\) is calculated from:
\[
\begin{equation*}
\operatorname{Pr}\left(D_{L}>r^{*}\right)=\frac{C_{h} Q^{*}}{C_{h} Q^{*}+\pi E(D)} \tag{5-45}
\end{equation*}
\]

In which
\[
\begin{equation*}
\pi=\pi_{0}+V-P \tag{5-44}
\end{equation*}
\]

Where
\[
\begin{array}{cl}
\mathrm{P} & \text { Purchase price per unit } \\
\mathrm{V} & \text { Sale price perunit } \\
\pi_{\circ} & \text { Lost sale cost/unit (other than lost profits) }
\end{array}
\]

If D is constant, D replaces \(\mathrm{E}(\mathrm{D})\).

\section*{5-7-1-1 Safety Stock in (r Q) - Lost Sale case}

When the lead time demand ( \(D_{L}\) or \(x\) ) is less than the reorder point, the quantity of product left is \(r-x\) with mean
\[
\begin{aligned}
& =\int_{0}^{r}(r-x) f_{D_{L}}(x) d x= \\
& \int_{0}^{\infty}(r-x) f_{D_{L}}(x) d x-\int_{r}^{\infty}(r-x) f_{D_{L}}(x) d x
\end{aligned}
\]
\[
\begin{aligned}
& =r \int_{0}^{\infty} f_{D_{L}}(x) d x-\int_{0}^{\infty} x f_{D_{L}}(x) d x-\int_{r}^{\infty}(r-x) f_{D_{L}}(x) d x \Rightarrow \\
& S S=r-E\left(D_{L}\right)+\int_{r}^{\infty}(x-r) f_{D_{L}}(x) d x
\end{aligned}
\]

Therefore in the optimum state
\[
S S=r^{*}-E\left(D_{L}\right)+\int_{r}^{\infty}(x-r) f_{D_{L}}(x) d x=r^{*-E}\left(D_{L}\right)+\bar{b}(r) \quad\left(\Delta_{-} \uparrow \uparrow\right)
\]
for ( r Q ) systems with lost sale when the lost sale cost per unit is known, \(S S=r^{*}-E\left(D_{L}\right)\) has also been introduced (Winston 1994, page 917); however the first one is more accurate because it takes shortage into consideration.

Example 5-31(Winston, 1994 pagep17)

Annual demand for a product which independent from the lead time is normally distributed: \(\mathrm{D} N\left(\mu_{\mathrm{D}}=1000, \sigma_{\mathrm{D}}=40\right)\).
Continuous review model with lost sale is used and we have:
\[
\mathrm{T}_{\mathrm{L}}=2 \text { weeks } \quad \mathrm{C}_{\mathrm{o}}=50 \quad \mathrm{C}_{\mathrm{h}}=10 / \mathrm{yr} \quad \mathrm{~V}=50 \quad \mathrm{P}=30 \quad \pi_{0}=20
\]

Find the order quantity, the optimal reorder point, and the safety stock.

\section*{Solution}
\[
\begin{aligned}
& \pi=\pi_{0}+\mathrm{V}-\mathrm{P}=20+50-30=40 \\
& \mathrm{Q}^{*}=\sqrt{\frac{2 \mathrm{C}_{0} \mathrm{E}(\mathrm{D})}{\mathrm{C}_{\mathrm{h}}}}=100 \\
& \operatorname{Pr}\left(\mathrm{D}_{\mathrm{L}}>\mathrm{r}^{*}\right)=\frac{\mathrm{C}_{\mathrm{h}} \mathrm{Q}^{*}}{\mathrm{C}_{\mathrm{h}} \mathrm{Q}^{*}+\pi \mathrm{E}(\mathrm{D})}=\frac{10 \times 100}{1000+(20+50-30)(1000)}=0.024 \\
& \mu_{\mathrm{D}}=1000 / \mathrm{yr} \rightarrow \mu_{\mathrm{D}_{\mathrm{L}}}=\frac{1000 \times 2}{52}=38.46 \\
& \sigma_{\mathrm{D}_{\mathrm{L}}}=\sqrt{\sigma_{\mathrm{D}}^{2} \mu_{\mathrm{L}}+\sigma_{\mathrm{L}}^{2} \mu_{\mathrm{D}}^{2}}=\sqrt{\sigma_{\mathrm{D}}^{2} \times \mu_{\mathrm{L}}+0 \times \mu_{\mathrm{D}}^{2}} \\
& \sigma_{\mathrm{D}}=40 / \mathrm{yr} \Rightarrow \sigma_{\mathrm{D}_{\mathrm{L}}}=\sigma_{\mathrm{D}} \sqrt{\mu_{\mathrm{L}}}=\sigma_{\mathrm{D}} \sqrt{\mathrm{~T}_{\mathrm{L}}}=40 \sqrt{\frac{2}{52}} \simeq 8 \\
& \mathrm{D}_{\mathrm{L}}=\mathrm{DT}_{\mathrm{L}} \sim \operatorname{Normal}\left(38.46, \sigma_{\mathrm{D}_{\mathrm{L}}}=8\right) \\
& \operatorname{Pr}\left(\mathrm{D}_{\mathrm{L}}>\mathrm{r}^{*}\right)=\operatorname{Pr}\left(\mathrm{Z}>\frac{\mathrm{r}^{*}-38.46}{8}\right)=0 / 024 \Rightarrow \frac{\mathrm{r}^{*}-38.46}{8}=\mathrm{Z}_{0.024}
\end{aligned}
\]

Using MATLALB command norminv:
\[
\mathrm{Z}_{0.024}=\operatorname{norminv}(1-0.024)=1.9774 \Rightarrow \mathrm{r}^{*}=54.3
\]

Table D could be used instead of MATLAB command norminv. \(\mathrm{r}^{*}=54.3\) states Whenever the level of inventory reaches 54 units,place an order of 100 units.
Calculation of safety stock:
\[
S S=r^{*}-E\left(D_{L}\right)=\Delta f / r-r \Lambda / 49=10 / \Delta f \cong 19
\]

More accurately :
\[
S S=r^{*}-E\left(D_{L}\right)+\bar{b}(r)
\]

Since the lead time demand is normally distributed:
\[
\begin{aligned}
& \bar{b}(r)=\sigma_{D_{L}} \times G_{U}(k) \\
& k=\mathrm{Z}_{.024}=1.98 \quad \overline{\mathrm{~b}}(\mathrm{r})=8 \times \mathrm{G}_{\mathrm{U}}(1.98)=0.072 \\
& S S=r^{*}-E\left(D_{L}\right)+\bar{b}(r)=54.3-38.46+0.07 \simeq 15.91
\end{aligned}
\]

\section*{Example 5-32}

The annual demand and order quantity are fixed and equal to \(\mathrm{D}=420\) and \(\mathrm{Q}=60\). \(\pi=\$ 10\) per unit. The lead time demand \(\left(D_{\mathrm{L}}\right)\) Is as follows:
\begin{tabular}{|c|l|l|l|l|l|l|l|l|}
\hline \(\mathrm{D}_{\mathrm{L}}\) & 10 & 11 & 12 & 13 & 14 & 15 & 16 & 17 \\
\hline Probabil. & 0.1 & 0.2 & 0.2 & 0.15 & 0.15 & 0.1 & 0.07 & 0.03 \\
\hline
\end{tabular}

A continuous review system with lost sale is used. Which of the following choices do you recommend to use as a reorder point in order to have an average annual shortage cost near 25 ?
a) 14
b) 15
c) 16
d) 17

\section*{Solution}

If the reorder point is taken 14 and \(D_{L}\) equals 10,11 , \(12,13,14\) we do not encounter shortage. But if it equals 15,16 , 17 shortage will happen. The following table shows \(\bar{b}(r)\), and
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 292 \\
\hline
\end{tabular}
its cost for this case and cases \(\mathrm{r}_{\mathrm{r}} 13,15,16\) and 17 . Note that the number of lead time in a year is approximately \(\frac{D}{Q}=\frac{420}{60}=7\).
\begin{tabular}{|c|c|c|c|c|c|}
\hline \(R O P(\mathrm{r}) \rightarrow\) & 13 & 14 & 15 & 16 & 17 \\
\hline \(D_{L}\) causing shortage & 14,15,16,17 & 15,16,17 & 16,17 & 17 & - \\
\hline Average shortage in 1 lead time \(\bar{b}(r)\) & \[
\begin{aligned}
& 1 \times 0.15+ \\
& 2 \times 0.1+ \\
& 3 \times 0.07+ \\
& 4 \times 0.03=0.68
\end{aligned}
\] &  & \[
\begin{aligned}
& 1 \times 0.07+ \\
& 2 \times 0.03 \\
& =0.13
\end{aligned}
\] & .\(^{1 \times 0.03}\) & 0 \\
\hline Average shortage cost \(\pi \times \bar{b}(r)\) & \[
\begin{aligned}
& 10 \times 0.68 \\
& =6.8
\end{aligned}
\] & \[
\begin{aligned}
& 10 \times 0.33 \\
& =3.3
\end{aligned}
\] & \[
\begin{aligned}
& 10 \times 0.13 \\
& =1.3
\end{aligned}
\] & \[
\begin{aligned}
& 10 \times 0.03 \\
& =0.3
\end{aligned}
\] & 0 \\
\hline Average annual shortage cost \(\pi \times \bar{b}(r) \times D / Q\) & \[
\begin{aligned}
& 6.8 \times 7 \\
& =47.6
\end{aligned}
\] & \[
\begin{aligned}
& 3.3 \times 7 \\
& =23.1
\end{aligned}
\] & \[
\begin{aligned}
& 7 \times 1.3 \\
& =9.1
\end{aligned}
\] & \[
\begin{aligned}
& 7 \times 0.3= \\
& 2.1
\end{aligned}
\] & 0 \\
\hline
\end{tabular}

Average annual shortage costs are shown in the last row of the table. The average annual shortage cost near 25 belongs to \(r_{=} 14\). Therefore choice "a" is the right choice

\section*{5-7-2 Lost sale (r Q) - Stockout cost/ outage ( \(g\) ) known}

In continuous review systems with lost sale if the shortage cost per outage and the pdf of the lead time density function is known, the relationship for optimum reorder point is(Tersine, 1994, page 225):
\[
\begin{equation*}
\frac{f_{D_{L}}\left(r^{*}\right)}{F_{D_{L}}\left(r^{*}\right)}=\frac{C_{h} Q}{g D} \tag{5-47}
\end{equation*}
\]

Proof:
Let \(a\) denote the expected number of shortages occurring in a year and the \(\mathrm{TC}_{\mathrm{ss}}\) denote the cost related to SS and shortage; then \(\mathrm{TC}_{\mathrm{ss}}=\mathrm{C}_{\mathrm{h}} \times \mathrm{SS}\) mean \(+\mathrm{g} \times \mathrm{a}\).

Although the average number of cycles in a year is \(\frac{D}{Q+\bar{b}(r)}\) (Tersine, 1994 page 22)but usually it is approximated with \(\frac{D}{Q}\). Therefore
\[
\begin{gathered}
a=\frac{D}{Q} \operatorname{Pr}\left(D_{L}>r\right)=\frac{D}{Q} \int_{r}^{\infty} f_{D_{L}}(x) d x \\
\mathrm{TC}_{\mathrm{ss}}=\mathrm{C}_{\mathrm{h}} \times\left\{r-E\left(D_{L}\right)+\int_{r}^{\infty}(x-r) f_{D_{L}}(x) d x\right\}+\mathrm{g} \times \frac{D}{Q} \int_{r}^{\infty} f_{D_{L}}(x) d x \\
\frac{d T C_{s s}}{d r}=\cdot \quad \Rightarrow C_{h}-C_{h} \operatorname{Pr}\left(D_{L}>r\right)-g\left(\frac{D}{Q}\right) f_{D_{L}}(r)=\cdot \Rightarrow
\end{gathered}
\]

The optimum reorder point \(\left(r^{*}\right)\) has a value which satisfies the following relationship \({ }^{1}\) :
\[
\begin{equation*}
\frac{f_{D_{L}}\left(r^{*}\right)}{F_{D_{L}}\left(r^{*}\right)}=\frac{C_{h} Q}{g D} \tag{5-49}
\end{equation*}
\]

\section*{Example 5-33}

The annual demand for product is normally distributed with mean 200 and standard deviation of 4 . A continuous review system with lost sale is used. The lead time demand is exponentially distributed with mean 50 . The shortage cost per outage is \(\mathrm{g}=\$ 1\). The order quantity is \(\mathrm{Q}=26\) and \(\mathrm{C}_{\mathrm{h}}=\$ 0.077 / \mathrm{yr}\). Find safety stock and optimal reorder point.

\section*{Solution}

\footnotetext{
\({ }^{1}\) The differentiation under integral sign used Leibniz's Rule.
}
\[
\begin{aligned}
& \frac{f_{D_{L}}\left(r^{*}\right)}{F_{D_{L}}\left(r^{*}\right)}=\frac{C_{h} Q}{g D} \Rightarrow \frac{\frac{1}{50} \mathrm{e}^{-\frac{1}{50}} \mathrm{r}^{*}}{1-\frac{1}{50} \mathrm{r}^{*}}=\frac{0.077 \times 26}{1 \times 200} \Rightarrow \mathrm{r}^{*}=55 \\
& S S=r-E\left(D_{L}\right)+\int_{r}^{\infty}(x-r) f_{D_{L}}(x) d x \\
& \mathrm{SS}=55-50+\int_{55}^{*}(\mathrm{x}-55) \frac{1}{50} \mathrm{e}^{-\frac{1}{50} \mathrm{x}} \mathrm{dx} \\
& \int_{55}^{*}(\mathrm{x}-55) \frac{1}{50} \mathrm{e}^{-\frac{1}{50} \mathrm{x}} \mathrm{dx}=\int_{55}^{*} \frac{\mathrm{x}}{50} \mathrm{e}^{-\frac{\mathrm{x}}{50}} \mathrm{dx}-55 \int_{55}^{*}-\frac{1}{50} \mathrm{e}^{-\frac{1}{50}} \mathrm{dx} \\
& 55 \int_{55}^{*}-\frac{1}{50} \mathrm{e}^{-\frac{1}{50}} \mathrm{dx}=55 \mathrm{e}^{-\frac{55}{50}} \\
& \frac{\mathrm{x}}{50}=\mathrm{u} \quad \mathrm{e}^{-\frac{\mathrm{x}}{50}} \mathrm{dx}=\mathrm{dv} \quad \int_{55}^{*} \frac{\mathrm{x}}{50} \mathrm{e}^{-\frac{\mathrm{x}}{50}} \mathrm{dx}=\int_{55}^{*} \mathrm{udv}= \\
& \frac{\mathrm{x}}{50}(-50) \mathrm{e}^{-\frac{\mathrm{x}}{50} \int_{55}^{*}-\int_{55}^{*}-\mathrm{e}^{-\frac{\mathrm{x}}{50}} \mathrm{dx}=105 \mathrm{e}^{-\frac{55}{50}}} \\
& \Rightarrow \mathrm{SS}=5+\int_{55}^{*}(\mathrm{x}-55) \frac{1}{50} \mathrm{e}^{-\frac{1}{50}} \mathrm{dx}=8+105 \mathrm{e}^{-\frac{55}{50}}-55 \mathrm{e}^{-\frac{55}{50}}=21.64
\end{aligned}
\]

\section*{Example 5-34}

The inventory system for a product is continuous review with lost sale. The weekly demand is uniformly distributed over [0 100]. The lead time is 2 weeks and \(\mathrm{Q}=26\). Find the optimum reorder point if \(\mathrm{g}=\$ 1\) and the annual holding cost per unit is \(\$ 7\).

\section*{Solution}

Using moment generating it could easily be shown that the product of a constant number c and a uniform random variable over the interval [ab] has a uniform distribution on [ca cb]. Therefore \(D_{L}=D T_{L}\) is uniformly distributed over \(\left[\begin{array}{ll}0 & 100\end{array}\right]\).
\[
\frac{\mathrm{f}_{\mathrm{D}_{\mathrm{L}}}\left(\mathrm{r}^{*}\right)}{\mathrm{F}_{\mathrm{D}_{\mathrm{L}}}\left(\mathrm{r}^{*}\right)}=\frac{\mathrm{C}_{\mathrm{h}} \mathrm{Q}}{\mathrm{gD}} \Rightarrow \frac{\frac{1}{200}}{\frac{\mathrm{r}^{*}-0}{200}}=\frac{7 \times 26}{1 \times \frac{100+0}{2} \times 52} \Rightarrow \mathrm{r}^{*} \simeq 14
\]
\[
\mathrm{SS}=r^{*}-E\left(D_{L}\right)+\int_{r^{*}}^{\infty}\left(x-r^{*}\right) f_{D_{L}}(x) d x
\]
\[
\mathrm{SS}=14-50+\int_{14}^{100}(\mathrm{x}-14) \frac{1}{200} \mathrm{dx} \simeq 19
\]

\subsection*{5.8 Periodic Review Inventory Model or (R, T ) policy or FOI system}

This section is concerned with continuous review inventory systems which is denoted by ( \(\mathrm{R}, \mathrm{T}\) ) or FOI. Figure 5-11 shows this model shematically
\begin{tabular}{|c|l|}
\hline \multicolumn{2}{|c|}{ Symbols } \\
\hline A & The inventory level at reorder point \\
\hline \(\bar{b}(R)\) & Average shortage in each cycle \\
\hline \(\bar{B}(R)\) & Average shortage per year \\
\hline\(D_{L+T}\) & The demand(consumption) during \(T_{L}+T\) \\
\hline\(f_{D_{T+L}(.)}(\) & pdf of consumption during \(\mathrm{T}+T_{L}\) \\
\hline g & Shortage cost per outage \\
\hline L & Lead time \\
\hline\(G_{U}(k)\) & Normal loss integral \\
\hline\(p\) & Service level, probability of lack of shortage during \(\mathrm{T}+T_{L}\) \\
\hline P & Purchase price \\
\hline \(\mathrm{Q}_{\mathrm{t}}\) & order quantity at time t \\
\hline \(\mathrm{R}=\mathrm{E}=\mathrm{Q}_{\mathrm{m}}\) & Desired maximum level of inventory \\
\hline T & the review interval (cycle time), the time between \\
\hline \(\mathrm{T}_{\mathrm{L}}\) & 2 successive orders \\
\hline\(\pi\) & shortage cost per unit \\
\hline
\end{tabular}

Fig 5-11 Periodic review(R, T) or FOI model
In this system every T time an order is placed in such a way that the order quantity makes the inventory level to a predetermined value denoted by R or \(\mathrm{Q}_{\mathrm{m}}\). R has is equal to a value that is sufficient for time \(T\); however when w place an order at the beginning of the lead time as much the lead time demand is deducted from the inventory at the time of placing the order. Therefore the predetermined value R is such that it covers the demand during the review interval (cycle time) and the lead time \(\left(T+T_{L}\right)\). With minor modification, the relationships given in the previous section for continuous review system can be used here. Since by definition, the service level is \(p=\operatorname{Pr}\left(D_{T+L} \leq R\right)\), then given a service level p . the dished R is calculated from:
\begin{tabular}{|l|l|l|}
\hline Demand & & \\
\hline Continu. & \(F_{D_{T+L}}(R)=p\) & \((5-50)\) \\
\hline Discrete & \(F_{D_{T+L}}(R) \geq p\) & \((5-51)\) \\
\hline
\end{tabular}

Where \(F_{D_{T+L}}\) (.) is the cumulative distribution function of \(D_{T+L}\), i.e. the demand during \(\mathrm{T}+\mathrm{T}_{\mathrm{L}}\).

The safety stock in this system is:
\[
\begin{equation*}
S S=R-E\left(D_{L+T}\right) \tag{5-52}
\end{equation*}
\]

Later it will be shown that if \(D_{L+T}\) is normally distributed with mean \(\mu_{D_{T+L}}\) and standard deviation \(\sigma_{D_{T+L}}\) then:
\[
R=Q_{m}=\mu_{D_{L+t}}+Z_{1-p} \times \sigma_{D_{L+t}}(5-53)
\]

The ordering Quantity is given by:
\[
\begin{equation*}
Q_{t}=Q_{m}-A=R-A \tag{5-54}
\end{equation*}
\]

Where
A The inventory level at reorder point
\(\mathrm{Q}_{\mathrm{t}} \quad\) The ordering quantity
\(\mathrm{R}=\mathrm{E}=\mathrm{Q}\) Maximum inventory level

The inventory level will never reach the maximum unless the lead time is negligible.

\section*{5-8-1 Determination of review interval( \(T\) ) in ( \(R, T\) ) model}

The review interval ( cycle time) is often set to:
\[
\begin{equation*}
T=\frac{Q_{w}}{E(D)} \tag{5-55}
\end{equation*}
\]
or may be determined empirically. Note to set \(C o\) when equal to the ordering cost plus the per cycle cost of reviewing the level of inventory.

\section*{Example 5-35}

In a period inventory system, it costs \(\$ 500\) to review the inventory and 5000 dollars to place an order for a kind of product. The average annual demand is 990 units. The holding cost per unit is \(\$ 100\) annually. What is your suggestion for the review interval.

\section*{Solution}
\[
\begin{aligned}
& T=\frac{Q_{W}}{\mu_{D}} \quad Q_{W}=\sqrt{\frac{2 \mu_{\mathrm{D}} \mathrm{C}_{\mathrm{o}}}{\mathrm{C}_{\mathrm{h}}}} \\
& Q_{w}=\sqrt{\frac{2 \times 990 \times(5000+500)}{100}}=330 \quad \mathrm{~T}=\frac{330}{990}=\frac{1}{3} \mathrm{yr} \\
& \text { or } \mathrm{T}=\sqrt{\frac{2 \mathrm{C}_{0}}{\mathrm{C}_{\mathrm{h}} \mu_{\mathrm{D}}}}=\sqrt{\frac{2 \times 5500}{100 \times 990}}=0.33 \mathrm{yr} \quad \boldsymbol{~}
\end{aligned}
\]

\section*{5-8-2 Calculation of maximum inventory( R )}

Given some service level (p) and the distribution of the demand during the lead rime plus the review time ( \(\boldsymbol{D}_{\boldsymbol{L + T}}\) ), the maximum inventory \((\mathrm{R})\) is calculated from the following relationship:
\[
\begin{equation*}
\operatorname{Pr}\left(D_{L+T} \leq R\right)=p \Rightarrow R=F^{-1}(p) \tag{5-56}
\end{equation*}
\]

\section*{5-8-3 Mean and Variance of L+T demand ( \(D_{L+T}\) )}

To deal with the mean and variance of consumption during the lead time plus the review time, 4 cases are distinguished as follows

Case 1: \(\operatorname{Demand}(D)\) and the lead time \(\left(\mathrm{L}=\mathrm{T}_{\mathrm{L}}\right)\) are independent random variables,

Case 2: Demand( D ) constant, the lead time \(\left(\mathrm{L}=\mathrm{T}_{\mathrm{L}}\right)\) random variable,

Case 3: Demand(D) random variable, the lead time ( \(\mathrm{L}=\mathrm{T}_{\mathrm{L}}\) ) constant,

Case 4: \(\operatorname{Demand}(\mathrm{D})\) and the lead time \(\left(\mathrm{L}=\mathrm{T}_{\mathrm{L}}\right)\) constant,
When using the relationships given in each case, be careful to differentiate between the mean and the variance of "annual or daily or weekly" demand and the mean and the variance of "T+L" demand.

\section*{5-8-3-1 Demand( \(D\) ) and the lead time \((L=T L)\) independent random variables}

According to Theorem 5-2, if the "annual or daily or weekly" demand denoted by D and the lead time denoted by \(\mathrm{L}=\mathrm{T}_{\mathrm{L}}\) are independent random variables, then the mean and variance of \(D_{L+T}\) the demand related to \(T+L\), are :
\[
\begin{gather*}
E\left(D_{L+T}\right)=E(D) \times E(T+L)  \tag{5-57}\\
\operatorname{Var}\left(D_{L+T}\right)=\mu_{T+L} \sigma_{D}^{2}+\mu_{D}^{2} \sigma_{T+L}^{2} \tag{5-58}
\end{gather*}
\]

Note that
T is not probabilistic, then \(\sigma_{T+L}^{2}=\sigma_{L}^{2}\),

T could determined from
\[
\begin{equation*}
T=\frac{Q_{w}}{D \text { or } E(D)}=\sqrt{\frac{2 C_{0}}{C_{h} \mu_{D}}} \tag{5-59}
\end{equation*}
\]

Furthermore in this model
\[
\begin{align*}
& \mathrm{R}=\mathrm{E}\left(\mathrm{D}_{\mathrm{L}+\mathrm{T}}\right)+\mathrm{SS}  \tag{5-60}\\
& \mathrm{SS}=\mathrm{R}-\mathrm{E}\left(\mathrm{D}_{\mathrm{L}+\mathrm{T}}\right)  \tag{5-61}\\
& \operatorname{Var}(\mathrm{T}+\mathrm{L})=\operatorname{Var}(\mathrm{L})  \tag{5-62}\\
& \mathrm{E}(\mathrm{~T}+\mathrm{L})=\mathrm{T}+\mu_{\mathrm{L}} \tag{5-63}
\end{align*}
\]

Special case: \(\mathrm{D}_{\mathrm{T}+\mathrm{L}}\) normally distributed
If \(\mathbf{D}_{\mathbf{T}+\mathbf{L}}\) is normally distributed, the for a given service level
\(\operatorname{Pr}\left(Z \leq \frac{R-E\left(D_{L+T}\right)}{\sigma_{D_{T+L}}}\right)=p\) then

\section*{Relationship for maximum inventory}
\[
\begin{equation*}
R \text { or } Q_{m}=\mu_{D_{L+T}}+Z_{1-p} \sigma_{D_{L+T}} \tag{5-64}
\end{equation*}
\]

Where
\[
\sigma_{D_{L+r}}=\sqrt{\mu_{T+L} \operatorname{Var}(D)+\mu_{D}^{2} \operatorname{Var}(T+L)} .
\]

\section*{Relationship for safety stock}

Since \(S S=R-E\left(D_{L+T}\right)\) then according to Eq. (5.64):
\[
\begin{equation*}
\mathrm{SS}=\mathrm{Z}_{1-\mathrm{p}} \sigma_{\mathrm{D}_{\mathrm{L}+\mathrm{T}}} \tag{5-65}
\end{equation*}
\]

Note: when replacing the values of the parameters in the equations be sure to have the same dimensions.

\section*{Example 5-35}

In a periodic review inventory system, the lead time(L) is normally distributed :Normal( 1 week, half week), the weekly demand is also normally distributed: \(\operatorname{Normal}(400,25)\) and independent from the lead time. The annual holding cost per unit is \(\mathrm{C}_{\mathrm{h}}=0.65\). Find the maximum inventory for a review time of 4 weeks and \(95 \%\) service level.

\section*{Solution}
\[
\begin{aligned}
& D_{L+T}=D\left(T+T_{L}\right), T_{L} \sim N\left(1, \frac{1}{r}\right) \Rightarrow T+T_{L} \sim \mathrm{~N}\left(5, \frac{1}{2}\right) \\
& \quad F_{D_{T+L}}(R)=p
\end{aligned}
\]

According to Theorem 5-2
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 300 \\
\hline
\end{tabular}
\[
\begin{aligned}
& E\left(D_{L+T}\right)=E\left[D \times\left(T+T_{L}\right)\right]=E(D) E\left(T+T_{L}\right)=400 \times 5=2000 \\
& \sigma_{D_{T+L}}=\sqrt{\mu_{T+L} \operatorname{Var}(D)+\mu_{D}^{2} \operatorname{Var}(T+L)} \\
& \sigma_{D_{L+T}}=\sqrt{5 \times 25^{2}+400^{2} \times \frac{1}{4}}=207.7
\end{aligned}
\]

Since both \(T+T_{L}\) and D are normally distributed, Sec. 1-6-1 allows us to approximate \(\mathrm{D}_{\mathrm{L}+\mathrm{T}}\) with \(D_{L+T} \sim N(2000,207.7)\) then
\[
\begin{aligned}
& \operatorname{Pr}\left(D_{L+T} \leq R\right)=p \quad \operatorname{Pr}\left(Z>\frac{R-E\left(D_{L+T}\right)}{\sigma_{D_{L+r}}}\right)=1-0.95 \\
& R=E\left(D_{L+T}\right)+Z_{\sigma_{r o}} \sigma_{D_{L+T}} \Rightarrow R=2000+1.6445 \times 207.7=2342
\end{aligned}
\]

5-8-3-2 Demand(D) random variables and the lead time( L
\(=T_{L}\) ) constant
\[
\begin{gather*}
D_{L+T}=D\left(T+T_{L}\right) . \text { If } \mathrm{D} \text { and } \mathrm{L}=\mathrm{T}_{\mathrm{L}} \text { are independent: } \\
E\left(D_{T+L}\right)=D E(T+L) \quad(5-66)  \tag{5-66}\\
\operatorname{Var}\left(D_{T+L}\right)=D^{2} \operatorname{Var}(T+L) \quad(5-67) \tag{5-67}
\end{gather*}
\]

\section*{5-7-3-3 Demand( \(D\) ) constant and the lead time ( \(L=T T_{L}\) )} random variables
\[
\operatorname{Var}(T+L)=0
\]

If D and \(\mathrm{L}=\mathrm{T}_{\mathrm{L}}\) are independent:
\[
\begin{align*}
& E\left(D_{L+T}\right)=E(D) \times(T+L)  \tag{5-68}\\
& \operatorname{Var}\left(D_{L+T}\right)=(T+L) \sigma_{D}^{2} \tag{5-69}
\end{align*}
\]

\section*{Special case: D normally distributed}

If demand is normally distributed, the consumption during \(\mathrm{T}+\mathrm{L}\)

Will be normally distributed:
\(D_{L+T} \sim \operatorname{Normal}\left(\mu=(T+L) \mu_{D} \quad, \quad \sigma=\sigma_{D} \times \sqrt{T+L}\right)\)
and
\[
\begin{gather*}
Q_{m}=R=(T+L) E(D)+Z_{1-p} \times \sigma_{D} \sqrt{T+L}  \tag{5-70}\\
S S=R-E\left(D_{T+L}\right)  \tag{5-71}\\
S S=Z_{1-p} \times \sigma_{D} \sqrt{T+L} \tag{5-72}
\end{gather*}
\]

Note
As mentioned in Sec 5-4-5-1-1,the variance of demand i.e. \(\operatorname{Var}(\mathrm{D})\) is expressed in \(\left(\frac{\text { units }^{2}}{\text { unit time }}\right)\) and \(\sigma_{D}\) in \(\left(\frac{\text { unit }}{\sqrt{\text { unit time }}}\right)\) then to convert the standard deviation of monthly demand to that of yearly demand, multiply it by \(\sqrt{12}\). For example \(\sigma_{D}=10\) units/month is equivalent to \(\sigma_{D}=10 \sqrt{12}\) units per year. To convert the variance of monthly or daily demand to that of yearly demand, multiply it by 12 or \(\mathrm{N}=\) no. of working days in a year respectively.5-8-3-4 Demand \((D)\) and the lead time \(\left(L=T_{L}\right)\) constant

If demand and \(\mathrm{T}_{\mathrm{L}}\) are non-probabilistic then
\[
S S=R-E\left(D_{L+T}\right)=D \times(T+L)-D \times(T+L)=0 .
\]

Let A denote the inventory level at the time of placing an order. R has to cover the demand during \(\mathrm{T}+\mathrm{L}\), then
\[
Q_{t}=D T-\left(A-D T_{L}\right)=D\left(T+T_{L}\right)-A \quad(5-73)
\]

\section*{5-7-4 Average shortage}

Let \(f_{D_{T+L}}(x)\) denotes the pdf of continuous X or \(\mathrm{D}_{\mathrm{T}+\mathrm{L}}\) (the demand during \(\mathrm{T}+\mathrm{L}\) ) and \(p_{D_{T+L}}(x)\) denotes the probability function of discrete X or \(\mathrm{D}_{\mathrm{T}+\mathrm{L}} . \bar{b}(R)\), the average shortage related to one cycle is calcu-
lated from the following integral or summation depending on the continuity or discreteness of \(D_{T+L}\).
\[
\bar{b}(R)=\left\{\begin{array}{l}
\int_{R}^{\infty}(x-R) f_{D}{ }_{T+L}(x) d x \\
\sum_{x>R}(x-R) p_{D+L}(x)
\end{array}\right.
\]
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 302 \\
\hline
\end{tabular}

The annual amount of shortage is derived from \(\bar{B}(R)=\bar{b}(R) \times \frac{1}{T}\) where T is the review time in year.

\section*{5-7-4-1 Average shotage, maximum inventory, safety stock} when \(D_{L+T}\) is normal

If the demand during \(\mathrm{L}+\mathrm{T}\) is normally distributed with mean and standard deviation \(E\left(D_{T+L}\right), \sigma_{D_{T+L}}\) then the average shortage in a cycle is:
\(\bar{b}(R)=\int_{R}^{\infty}(x-R) \frac{1}{\sigma_{L+T} \sqrt{2 \pi}} e^{-\frac{\left(x-\mu_{D_{L+T}}\right)^{2}}{2 \sigma_{D_{L+T}}^{2}}} d x\)
Using normal Loss integral mentioned in Sec 1-5-1:
\(\bar{b}(R)=\sigma_{D_{L+T}} G_{U}(k) \quad k=\frac{R-\mu_{D_{L+T}}}{\sigma_{D_{L+T}}}\)
Where
\(k=Z_{1-p}=\frac{R-\mu_{D_{T+L}}}{\sigma_{D_{T+L}}}\) and \(G_{U}(k)\) is the loss normal intergral whose value is obtained from Table A or the following command

GUk=exp(-k^2/2)/sqrt(2*pi)-k*(1-normcdf(k)).
The following table summarized some of the above relationships.
\begin{tabular}{|l|r|c|}
\hline \multicolumn{3}{|c|}{ Some relationships used in (R T) \(=\) FOI system } \\
\hline Review time & \(=\) & \(T^{*}=\frac{Q_{W}}{\mu_{D}}=\sqrt{\frac{2 C_{0}}{C_{h} \mu_{D}}}\) \\
\hline Annual shortage & \(=\) & \(\bar{B}(R)=\frac{\bar{b}(R)}{\mathrm{T}^{*}}\) \\
\hline \begin{tabular}{l} 
The ration of annual \\
shortage to annual demand
\end{tabular} & \(=\) & \(\frac{\bar{B}(R)}{D}=\frac{\bar{b}(R)}{D T^{*}}\) \\
\hline Average inventory & \(=\) & \(\bar{I}=\frac{D T^{*}}{2}+S S\) \\
\hline \begin{tabular}{l} 
Average no. of \\
shortages in a year
\end{tabular} & \(=\) & \(N_{b}=\frac{1}{T^{*}} \operatorname{Pr}\left(D_{L+T}>R\right)=\frac{1-p}{T^{*}}\) \\
\hline \begin{tabular}{l} 
Average time between 2 \\
successive shortages
\end{tabular} & \(=\) & \(\frac{T^{*}}{1-p}=\frac{1}{N_{h}}\) \\
\hline
\end{tabular}
\begin{tabular}{|l|l|l|}
\hline Safety stock & \(=\) & \(\mathrm{SS}=R-E\left(D_{L+T}\right)\) \\
\hline SS if \(\mathrm{D}_{\mathrm{L}+\mathrm{T}}\) is normal & \(=\) & \(Z_{\vdash-p} \sigma_{D_{L+T}}\) \\
\hline \begin{tabular}{l} 
Average shortage in \\
cycle if \(\mathrm{D}_{\mathrm{L}+\mathrm{T}}\) is normal
\end{tabular} & \(=\) & \(\bar{b}(R)=\sigma_{D_{L+T}} \times G_{U}(k)\) \\
\hline
\end{tabular}

Note
-If safety stock is not requited in a periodic review system then \(R=E\left(D_{T+L}\right)+S S=E\left(D_{T+L}\right)\)
- In FOI model the order quantity for all cycles is not the same.
- Using the following transforms FOS relationships are converted into FOI ones(Sabahno,2008, page 4):
\begin{tabular}{|l|l|l|}
\hline FOS \(=\left(\begin{array}{ll}\mathrm{r} & \text { Q }) \\
\mathrm{L} & \\
\hline \mathrm{FOI}=\left(\begin{array}{ll}\mathrm{R} & \mathrm{T}\end{array}\right) \\
\hline \mathrm{r} & \rightarrow \\
\mathrm{L}+\mathrm{T} \\
\hline \mathrm{Q} & \rightarrow \\
\mathrm{R} \\
\hline\end{array} \mathrm{D}\right.\) & \\
\hline
\end{tabular}

\section*{Example 5-37}

The annual demand for a product is 18000 , each order costs \(\$ 5000\), annual holding cost per unit is \(\$ 25\) and the lead time is 2 days for a kind of product which is ordered every fixed time T. Assuming a 90\% service level in (R T) model, find economic T, maximum inventory, average inventory, average shortage per cycle and per year. The demand during \(t\) days is approximated with \(\mathrm{N}(\mu=15 \mathrm{t}, \sigma=4 \sqrt{\mathrm{t}})\). There are 360 working days in a year. Calculate safety stock as well.

\section*{Solution}
\[
\begin{aligned}
& T^{*}=\sqrt{\frac{2 C_{o}}{D C_{h}}}=\sqrt{\frac{2 \times 5000}{25 \times 18000}} \Rightarrow \\
& T^{*}=\frac{150}{1000} \mathrm{yr}=\frac{150}{1000} \times 360 \cong 50 \text { days }
\end{aligned}
\]
\[
\begin{aligned}
& k=\frac{R-E\left(D_{L+T}\right)}{\sigma_{D_{L+T}}}=Z_{0.1} \\
& \frac{\mathrm{R}-1300}{4 \sqrt{52}}=1.28 \Rightarrow R=Q_{m} \cong 1337
\end{aligned}
\]

Note in this problem the lead time is constant as well as the review time; then \(\mathrm{T}+\mathrm{L}\) is constant and fixed.
\[
\begin{aligned}
& \mathrm{D}_{\mathrm{L}+\mathrm{T}} \sim \operatorname{Normal}(\mu=15(\mathrm{~L}+\mathrm{T}), \sigma=4 \sqrt{\mathrm{~L}+\mathrm{T}}) \\
& \mathrm{E}\left(\mathrm{D}_{\mathrm{L}+\mathrm{T}}\right)=15(2+50)=1300 \\
& \sigma_{\mathrm{D}_{\mathrm{L}+\mathrm{T}}}=4 \sqrt{\mathrm{~L}+\mathrm{T}}=4 \sqrt{52} \simeq 28.8 \\
& \operatorname{Pr}\left(\mathrm{D}_{\mathrm{L}+\mathrm{T}} \leq \mathrm{R}\right)=\mathrm{p}=0.90 \rightarrow \operatorname{Pr}\left(\mathrm{Z}>\frac{\mathrm{R}-\mathrm{E}\left(\mathrm{D}_{\mathrm{L}+\mathrm{T}}\right)}{\sigma_{\mathrm{D}_{\mathrm{L}+\mathrm{T}}}}\right)=1-\mathrm{p}=0.1
\end{aligned}
\]

Every 50 days an order with the following quantity has to placed
\[
\begin{aligned}
& Q_{t}=Q_{m}-A=R-A \quad R=Q_{m}=1337 \\
& \mathrm{SS}=? \\
& S S=k \sigma_{D+L}=Z_{\cdot / /} \sigma_{D+L}=1.28 \times 4 \sqrt{52} \cong 37 \\
& \bar{b}(\mathrm{R})=\sigma_{\mathrm{D}_{\mathrm{T}+\mathrm{L}}} \times \mathrm{G}_{\mathrm{U}}(\mathrm{k}) \quad \mathrm{k}=\mathrm{Z}_{1-\mathrm{p}}=\mathrm{Z}_{0.025}=1.28 \\
& \mathrm{G}_{\mathrm{U}}(1.28)=0.0475: \text { Table A } \\
& \overline{\mathrm{b}}(\mathrm{R})=4 \sqrt{52} \times 0.0475 \cong 1.37 \\
& \overline{\mathrm{~B}}(\mathrm{R})=\overline{\mathrm{b}(\mathrm{R})} \times \frac{1}{\mathrm{~T}^{*}}=1.37 \times \frac{1}{\frac{50}{360}} \cong 10
\end{aligned}
\]

\section*{Example 5-38 \({ }^{1}\)}

A product is ordered every T time to reach the inventory to its maximum R. If the monthly demand(D) is variable with mean \(E(D)\) and the lead time is deterministic, find an expression for the mean inventory \((\bar{I})\) :

\section*{Solution}
\(\overline{\mathrm{I}}=\frac{\mathrm{Q}}{2}+\mathrm{SS}=\frac{\mathrm{DT}}{2}+\mathrm{SS} \quad \mathrm{SS}=\mathrm{R}-\mathrm{E}\left(\mathrm{D}_{\mathrm{T}+\mathrm{L}}\right)=\mathrm{R}-(\mathrm{L}+\mathrm{T}) \times \mathrm{E}(\mathrm{D})\)
\(\bar{I}=\frac{T \times E(D)}{2}+R-L \times E(D)-T \times E(D), \bar{I}=R-L \times E(D)-\frac{T}{2} \times E(D)=R-E(D)\left[L-\frac{T}{2} E(D)\right]\)
End of example

\section*{Example 5-39 \({ }^{2}\)}

A kind of product is ordered every 3 months. The lead time is one month. The demand during t days is approximated with \(\mathrm{N}(\mu=\mathrm{t}, \sigma=\) \(10 \sqrt{\mathrm{t}}\) ). With a service level of \(90 \%\), calculate the maximum inventory.

\section*{Solution}

In this problem the lead time is constant as well as the review time; then \(\mathrm{T}+\mathrm{L}\) is constant and fixed. Since D is normally distributed \(D_{L+T}\) is normally distributed : \(D_{L+T} \sim \operatorname{Normal}\left(E\left(D_{L+T}\right), \sigma_{D_{L+T}}\right)\) :
\(\left\{\begin{array}{l}\mathrm{E}\left(\mathrm{D}_{\mathrm{L}+\mathrm{T}}\right)=(3+1)(100)=400 \\ \sigma_{\mathrm{D}_{\mathrm{L}+\mathrm{T}}}=10 \sqrt{3+1}=20\end{array}\right.\)
\(p=\operatorname{Pr}\left(D_{L+T} \leq R\right)=0.9\) then

\footnotetext{
\({ }^{1}\) Iranian Universities entrance Exam (from Asadzadeh et al(2006) page 226
\({ }^{2}\) Asadzadeh et al(2006) page 233
}

\section*{Chapter 5 Inventory control under uncertainty}
\[
\begin{aligned}
& \operatorname{Pr}\left(Z>\frac{R-E\left(D_{L+T}\right)}{\sigma_{D_{L+T}}}\right)=1-p=0.1 \\
& \Rightarrow \frac{R-E\left(D_{L+T}\right)}{\sigma_{D_{L+T}}}=\mathrm{Z}_{0.1}=1.28 \\
& \quad=\mathrm{Z}_{0.1} \\
& R=E\left(D_{L+T}\right)+Z_{1-p} \sigma_{D_{L+T}} \\
& \mathrm{R}=400+1.28 \times 20 \simeq 425.6
\end{aligned}
\]

If the inventory level at the time of ordering is A the order quantity would be \(Q=425-A\)

\section*{Example 5-40}

A kind of product is ordered every 3 months. The lead time is two weeks. The service level is \(90 \%\) and he demand during \(\mathrm{T}+\mathrm{L}\) is given in the following table, Find shortage probability, average shortage in each cycle and the safety stock
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline\(X=D_{L+T}\) & 50 & 60 & 70 & 80 & 90 & 100 \\
\hline Prob. & 0.1 & 0.1 & 0.2 & 0.3 & 0.2 & 0.1 \\
\hline Cum. & 0.1 & 0.2 & 0.4 & 0.7 & 0.9 & 1 \\
\hline
\end{tabular}

\section*{Solution}
\[
\begin{aligned}
& \quad \text { shortage probability }=1-0.9=0.1 \\
& \operatorname{Pr}\left(D_{L+T} \leq R\right)=0,9 \Rightarrow R=90 \\
& \bar{b}(R)=\sum_{x>R}(x-R) p_{D_{L+T}}(x)= \\
& \sum_{x>90}(\mathrm{x}-90) \mathrm{p}_{\mathrm{X}}(\mathrm{x})=(100-90) \times 0.1=1 \\
& S S=R-E\left(D_{L+T}\right)=90-(50 \times 0.1+60 \times 0.1+\ldots .+100 \times 0.1) \\
& \mathrm{SS}=13
\end{aligned}
\]

\section*{Shortage in periodic review systems}

When the demand(D) is greater than the maximum inventory \((\mathrm{R})\) some policies including the following ones might be adopted to remedy this situation:
complete backordering,
complete lost sale.
These two are dealt in detail below.

\section*{5-9 Back ordering in FOI system}

In this section complete backordering is assumed in periodic review inventory systems and 2 cases are distinguished : either the shortage cost per unit or the shortage cost per outage is k.nown.

\section*{5-9-1 Backordered (R T) - Stockout cost/ unit ( \(\pi\) )known}

If the stockout cost per unit ( \(\boldsymbol{\pi}\) ) is known \(\boldsymbol{R}^{*}\), the maximum inventory in its optimum state, is calculated from (Tersine, 1994 p 244 ):
\[
\begin{equation*}
\operatorname{Pr}\left(D_{L+T}>R^{*}\right)=\frac{C_{h} T^{*}}{\pi} \tag{5-77}
\end{equation*}
\]

If \(\frac{C_{h} T^{*}}{\pi}>1\),there would not be an answer for \(\boldsymbol{R}^{*}\),

\section*{Example 5-41}

The lead time for ordering a product is normally distributed with mean of one week and variance of \(\frac{1}{4}\) and the weekly demand has a normal distribution \(\mathrm{N}(\mu=400, \sigma=25)\) and is independent of the lead time. Shortage is backord at the cost of one dollar per unit. The a holding cost per unit is \(\$ 0.65\). Find the optimal value of the maximum invean FOI mode used with a 4-week period review,

\section*{Chapter 5 Inventory control under uncertainty}

\section*{Solution}
\[
\begin{aligned}
& D_{L+T}=D\left(T+T_{L}\right) \\
& T_{L} \sim N\left(1, \frac{1}{\gamma}\right) \Rightarrow T+T_{L} \sim N\left(0, \frac{1}{\gamma}\right)
\end{aligned}
\]

According to Sec 1-6-1 \(\boldsymbol{D}_{\boldsymbol{T}+\boldsymbol{L}}\) is approximately normally distributed

\section*{with}
\[
E\left(D_{L+T}\right)=E\left[D\left(T+T_{L}\right)\right]=E(D) E\left(T+T_{L}\right)=400 \times 5=2000
\]
\[
\sigma_{D_{T+L}}=\sqrt{\mu_{T+L} \operatorname{Var}(D)+\mu_{D}^{2} \operatorname{Var}(T+L)}=207.7
\]
\[
\operatorname{Pr}\left(D_{L+T}>R^{*}\right)=\frac{C_{h} T^{*}}{\pi}
\]
\[
\operatorname{Pr}\left(Z>\frac{R^{*}-E\left(D_{L+T}\right)}{\sigma_{D_{L+T}}}\right)=\frac{C_{h} T^{*}}{\pi}=\frac{0.65 \times \frac{4}{52}}{1}=0.05
\]
\[
R^{*}=E\left(D_{L+T}\right)+\mathrm{Z}_{0.05} \sigma_{D_{L+T}} \Rightarrow R^{*}=2000+1.6445 \times 207.7=2342
\]

\section*{5-9-2 Backordered (R T) - Stockout cost/ outage (g) known}

If the cost per outage is known then the optimal value of the maximum inventory is calculated from (Tersine,1994, page244):
\[
\begin{equation*}
f_{D_{L+T}}\left(R^{*}\right)=\frac{C_{h} T}{g} \tag{5-78}
\end{equation*}
\]

\section*{Example 5-42}

Solve the previous example supposing \(g=\$ 200\) fot the cost per outage and ignore \(\boldsymbol{\pi}\).

\section*{Solution}
\[
\begin{aligned}
& \text { annual } C_{h}=0.65 \sigma_{\sigma_{D_{L+T}=207.7}} \mu_{D_{L+T}=2000} T=\frac{4}{52} y r \\
& f_{D_{L+T}}\left(R^{*}\right)=\frac{C_{h} T^{*}}{g} \Rightarrow \frac{1}{\sigma_{D_{L+T}} \sqrt{2 \pi}} e^{-\frac{\left(R^{*}-\mu_{D_{L+T}}\right)^{2}}{2 \sigma_{D_{L}+T}^{2}}}= \\
& \frac{C_{h} T}{g}=\frac{0.65 \times \frac{4}{52}}{200} \Rightarrow \\
& \frac{R^{*}-2000}{207.7}= \pm 2.0194 \rightarrow R^{*}=2419 \& 1580
\end{aligned}
\]

\section*{5-10 Lost sale case in FOS system}

In this section complete lost sale is assumed in periodic review inventory systems and 2 cases are distinguished : either the shortage cost per unit or the shortage cost per outage is k.nown.

\section*{5-10-1 Lost sale (R T) - Stockout cost/ unit ( \(\boldsymbol{\pi}\) )known}

If the stockout cost per unit ( \(\boldsymbol{\pi}\) ) is known \(\boldsymbol{R}^{*}\), the maximum inventory in its optimum state, is calculated from (Tersine, 1994p244):
\[
\operatorname{Pr}\left(D_{L+T}>R^{*}\right)=\frac{C_{h} T}{\pi+C_{h} T} \quad(5-79)
\]

\section*{5-10-2 Lost sale (R T) - Stockout cost/ outage (g)known}

If the cost per outage is known then the optimal value of the maximum inventory is calculated from (Tersine,1994,page244):
\[
\begin{equation*}
\frac{f_{D_{L+T}}\left(R^{*}\right)}{F_{D_{L+T}}\left(R^{*}\right)}=\frac{C_{h} T}{g} \tag{5-80}
\end{equation*}
\]

\section*{Example 5-43}

The demand during \(\mathrm{L}+\mathrm{T}\) is approximately exponentially distributed with mean 500 units, the cost per outage is \(\$ 20\). A periodic review system is used with four-week review time. Find the optimal value of the maximum inventory if the annual holding cost per unit is \(\$ 0.65\).

\section*{Solution}
\[
\begin{aligned}
& \frac{f_{D_{L+T}}\left(R^{*}\right)}{F_{D_{L+T}}\left(R^{*}\right)}=\frac{C_{h} T^{*}}{g} \Rightarrow \\
& \frac{\frac{1}{500} \mathrm{e}^{-\frac{\mathrm{R}^{*}}{500}}}{1-\mathrm{e}^{-\frac{\mathrm{R}^{*}}{500}}}=\frac{0.65 \times \frac{4}{52}}{20} \Rightarrow \frac{\frac{1}{500} \mathrm{e}^{-\frac{\mathrm{R}^{*}}{500}}}{1-\mathrm{e}^{-\frac{\mathrm{R}^{*}}{500}}=0.0025 \Rightarrow} \\
& \mathrm{e}^{-\frac{\mathrm{R}^{*}}{500}}=\frac{25}{45} \Rightarrow R^{*} \cong 294
\end{aligned}
\]

\section*{5-11Inventory control under complete uncertainty}

Since dealing with inventory control under complete uncertainty and ambiguity needs some knowledge of decision making under uncertainty, a short description of the subject with emphasis on its application to inventory follows.

Decision theory can indirectly assist in defining the problem and in identifying alternatives, while directly helping to evaluate the alternatives(McKenna, 1980).

\section*{Definitions}

\section*{Action space}

The set of alternative actions from which a decision maker could choose an action to cope with a situation which needs a decision.

\section*{States of the real world or states of the nature}

The set of the events that may happen after an alternative action is chosen and performed by the decision maker is often referred to as "states of the nature" or "states of the world" and is beyond the control of the decision maker. In this section the set is denoted by \(\Theta=\left\{\theta_{1}, \theta_{2} \ldots\right\}\) An example of it in inventory control is the level of demand for a particular product.

\section*{Objective function}

In decision making a decision situation can involve one objective or more objectives. The objective function could be a desired quantity such as profit or an undesired one like cost or loss. We focus here on minimizing the objective function of the inventory cost as a single objective decision-making problem in inventory control under uncertainty.

To evaluate the alternative actions and choosing the appropriate one, a table similar to the following could be prepared. The possible actions being considered by the decision maker and the states of the real world are inserted in the table. Also the cost or the loss for "each action and each real world state" is calculated and inserted in the table.
\begin{tabular}{lll}
\hline Chapter 5 & Inventory control under uncertainty & 312 \\
\hline
\end{tabular}
\begin{tabular}{|c|c|c|}
\hline \multicolumn{3}{|c|}{ Loss function for action \(a_{\mathrm{i}}\) and natural state \(\theta_{\mathrm{j}}\)} \\
\hline Action & \multicolumn{2}{|c|}{ States of the nature } \\
\cline { 2 - 3 } & \(\theta_{1}\) & \(\theta_{2}\) \\
\hline \(\mathrm{a}_{1}\) & \begin{tabular}{c} 
The cost of action \\
\(\mathrm{a}_{1}\) if \(\theta_{1}\) happens
\end{tabular} & \begin{tabular}{c} 
The cost of action \\
\(\mathrm{a}_{1}\) if \(\theta_{2}\) happens
\end{tabular} \\
\hline\(a_{2}\) & \begin{tabular}{c} 
The cost of action \\
\(a_{2}\) if \(\theta_{1}\) happens
\end{tabular} & \begin{tabular}{c} 
The cost of action \\
\(a_{2}\) if \(\theta_{2}\) happens
\end{tabular} \\
\hline \(\mathrm{a}_{3}\) & \begin{tabular}{c} 
The cost of action \\
\(\mathrm{a}_{3}\) if \(\theta_{1}\) happens
\end{tabular} & \begin{tabular}{c} 
The cost of action \\
\(a_{3}\) if \(\theta_{2}\) happens
\end{tabular} \\
\hline
\end{tabular}

Then one of the actions is selected using the rules or criteria discussed below.

\section*{5-11-1 Decision criteria in minimization problems}

The process of selecting an action when an objective function is to be optimized is usually done using some common sense rules or criteria including the minimax decision criterion(rule), the minimin decision rule and the expected value decision criterion (Bayes method). In the following discussion the objective function is assumed to be cost.

\section*{The minimax decision criterion(rule)}

For each action determine the worst outcome, the minimax rule chooses the action with the "best" worst outcome When the objective function is the cost or loss, the minimax decision maker examines the possible cost for each alternative and takes particular note of the greatest cost for each alternative . He then chooses the alternative that yields the smallest of those maximum costs. The decision maker who chooses this criterion is more a pessimist than an optimist (based on Wiston, 1994 page 728 and McKenna ,1980 chap4)

\section*{The minimin decision rule}

For each action determine the best outcome, the miniin rule chooses the action with the "best" best outcome. When the objective function is the cost or loss, the minimin decision maker examines the possible cost for each alternative action and takes particular note of the minimum cost for each alternative . He then chooses the alternative that yields the smallest of those minimum costs. The decision maker who chooses this criterion is more an optimist than a pessimist .

\section*{The expected value criterion (Bayes method)}

If there is some basis for believing that one state of nature is more likely than the others, a weighted average of the function is preferable to a straight average . The weighted average, in which the probabilities arc the weights, is called the expected value criterion( McKenna,1980). When the objective function is the cost or loss. The expected cost is the sum of the products of probability times cost for each of the decision alternatives. The expected value decision maker chooses the alternative with the best expected cost.
Example 5-44
Suppose the demand for a product is 10 or 30 or 50 or 70 . We could order 20 or 40 or 60 units . The loss due each combination of demand and order size is given the following table. Determine the order size separately for the product using the above rules.
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multirow[t]{3}{*}{} & \multicolumn{5}{|l|}{The loss for each combination \({ }^{1}\)} \\
\hline & & \multicolumn{4}{|l|}{States of the Nature} \\
\hline & & \(\mathrm{D}=10\) & \(\mathrm{D}=30\) & \(\mathrm{D}=50\) & \(\mathrm{D}=70\) \\
\hline \multirow[t]{4}{*}{} & 20 & 50 & 270 & 1150 & 2030 \\
\hline & 40 & 480 & 100 & 380 & 1280 \\
\hline & 60 & 900 & 520 & 200 & 480 \\
\hline & 80 & 1045 & 665 & 345 & 250 \\
\hline Probab & & 0.2 & 0.4 & 0.4 & 0.1 \\
\hline
\end{tabular}

\section*{Solution}

\section*{a)MiniMax criterion}

For each action the worst loss is determined:
alternative Maximum Loss

Ordering 20 units \(\quad 2030=\max \{50,270,1150,2030\}\)
Ordering 40 units 1280
Ordering 60 units 900
Ordering 80 units 1045
the minimax decision maker chooses the alternative action with the "best" outcome i.e. chooses to order 60 units.

\footnotetext{
\({ }^{1}\) Note that this is an example and the costs are not real.
}
\begin{tabular}{lll} 
Chapter 5 & Inventory control under uncertainty & 314 \\
\hline
\end{tabular}

\section*{b)MiniMin criterion}

For each action the minimum loss is determined:
\begin{tabular}{ll} 
alternative & Minimum Loss \\
Ordering 20 units & \(50=\min \{50,270,1150,2030\}\) \\
Ordering 40 units & 100 \\
Ordering 60 units & 200 \\
Ordering 80 units & 250
\end{tabular}
the minimin decision maker chooses the alternative action with the "best" outcome i.e chooses to order 20 units.

The minimax rule chooses the action with the "best" worst outcome.
c) Expected value criterion

The following table shows the sum of the products of probability times cost loss for each of the decision alternatives . This value is average loss for the corresponding action.
\begin{tabular}{|c|c|}
\hline \begin{tabular}{l} 
Order \\
size
\end{tabular} & Average Loss \\
\hline 20 & \(50^{*} .2+270^{*} .4+1150^{*} .3+2030^{*} .1=666\) \\
\hline 40 & \(480^{*} .2+100^{*} .4+380^{*} .3+1280^{*} .1=378\) \\
\hline 60 & \(900^{*} .2+520^{*} .4+200^{*} .3+480^{*} .1=496\) \\
\hline 80 & \(1045^{*} .2+665^{*} .4+345^{*} .3+250^{*} .1=603\) \\
\hline
\end{tabular}

The expected value decision maker chooses 40 units as the order size because it has the best expected cost. Exercises \({ }^{1}\)
5.1 An industrial distributor sells water pumps and other related supplies. A particular water pump is purchased for \(60 \$\) from the manufacturer. The average sales per day are 5 units, and ihe annual holding cost is \(25 \%\) of the unit cost. The annual demand for the pump is 1500 units, and (he order quantity is 300 units. The backorder cost per unit is \(\$ 50\). and the lead time is 20 days. The demand during lead lime is given in the table below:
\begin{tabular}{|r|l|l|l|l|l|l|l|}
\hline \(\boldsymbol{D}_{\boldsymbol{L}}\) & 70 & 80 & 90 & 100 & 110 & 120 & \\
\hline frequency & 3 & 3 & 4 & 80 & 6 & 4 & Sum=100 \\
\hline
\end{tabular}
\({ }^{1}\) Problems 1 through 4 are from chapter 5 Tersine(994) p247 problems 1, \(2,3,4\). Problems \(8,9,12,21\) of chapter 5 , Tersine(994) p247 were also given to the students
a)what is the reorder point?
b)How much safety stock should be carried?
c)What is the expected annual cost of the safety stock?
5.2 An automotive parts dealer sells 1200 carburetors a year. Each carburetor costs \(\$ 25\), and the average demand is 4 units/day. The order quantity is 120 units, and the lead time is 25 days. The backorder cost per unit is \(\$ 20\), and annual holding cost is \(20 \%\) of unit cost. The lead time demand is given in the table below. Determine the safety stock level and the reorder point.
\begin{tabular}{|c|l|l|l|l|l|l|l|}
\hline \(\mathrm{D}_{\mathrm{L}}\) & 115 & 110 & 105 & 100 & 95 & 90 & \\
\hline frequency & 10 & 15 & 20 & 5 & 25 & 25 & Sum=100 \\
\hline
\end{tabular}
5.3 Solve again Problem 5-1 with the assumption that \(D_{L}\) is normally distributed with mean 100 units and variance 25
5.4 What should be the safety stock in Problem 5.2 if the lost sale cost per unit is \(\$ 20\) ?

\section*{Chapter 6 Introduction to Forecating Methods}

\section*{Chapter 6}

\section*{Introduction to Forecasting Methods}

\section*{Aims of the chapter}

This chapter describes some forecasting methods used in inventory management. The emphasis is on quantitative methods such as regression, time series methods, moving average, exponential smoothing . Some criteria such as RMSE are introduced to evaluate methods effectiveness. The application of quality control charts to verify whether a forecaster fits the case or not.

\section*{Symbols}

\section*{6-1 Introduction}

Forecasting is to identify the picture of the future events and conditions as close as to what it will happen. Although forecasting is rarely perfect and error-free, it cannot be discarded, and is used vastly in many subjects such as engineering and economics (including demand forecasting for goods and services). It is worth mentioning that forecasting is an art before being a science. In science the input is the rules of the nature, while the input of forecasting is data, analysis, experience and judgment. There is no rule in the nature giving a relationship between demand, for example and some other variables. It is because factors such as economic conditions, the
actions of the rivals and other social phenomena are complex. It should be emphasized that To find an appropriate method and effective use of it, human judgment will be a complement to the method .

\section*{6-2 Classification of Forecasting Methods}

Various methods are used for forecasting from a thought or simple statement to mathematical equations. Forecasting methods could be subjective or objective. The former are based on the opinion of the consumers or experts and use more intuitive or qualitative approaches . These methods are used when there is little

Fig 6.1 A Classification of Forecasting Methods
or no historical data. The former methods use quantitative or mathematical approaches. It is worth mentioning that when an objective method uses a mathematical formula to predict a variable, the method could be called a forecasting model. Figure 6-1 shows more classification of forecasting methods.

\section*{6-3 Subjective or qualitative Methods}

Subjective forecasting methods are based on common sense. The Forecaster use judgment and self-expertise for forecasting. Some of well-known subjective methods are:

Market research or users' expectation, Executive opinions, Delphi expertise method, Field sales force.
Below Delphi method is described.

\section*{6-3-1 Delphi Technique}

The Delphi technique is designed to obtain the opinions on a specific topic by means of a questionnaire delivered to selected experts of the subject.

This technique is designed to remedy some of the problems which arise in consensus forecasts. The technique attempts to maximize the advantages of group dynamics while minimizing the problems caused by dominant personalities and silent experts.(Terine, 1994, page 71). Steps of the method are as follows:
1. Define the problem and the questions for a group of selected experts electronically or physically.
2. Take the group's view as Round 1
3. Explore and discuss the different points of view with the group.
4. Take the groups view again as Round 2
5. Repeat step 2 and 3; ask for Round 3 (if consensus is reached at Round 2, Round 3 is unnecessary)

This is an iterative process and continues until you feel you have reached consensus with your group or sufficient information has been exchanged among the experts.

\section*{6-4 Objective or quantitative Methods}

Quantitative methods use a mathematical model or expression to illustrate the relations between a dependent variable (response) and some independent variables. These methods are used when there is enough historical data. If there is good knowledge of the relation between the dependent and independent variables, then casual models such Quantitative methods use a mathematical model or expression to illustrate the relations between a dependent as regression are used otherwise neural networks and data mining could be used. If the data is given in time series \({ }^{1}\), such model as exponential soothing, moving average, autoregressive auto-regressive moving average (ARMA), autoregressive integrated moving average(ARIMA) or artificial intelligence algorithms such as neural network modeling might be used.

\section*{6-4-1 Regression}

In many experiments a variable varies when the values of some other variables are changed during the \(\exp [m e r r i m e n t\). Regression models are used when there exists some inherent relationship among some variables and we want to predict the values of response variable(s) when the values of some independent variables change.

A mathematical equation that allows us to predict values of one dependent variable from known values of one or more independent variables is called a regression equation

\footnotetext{
\({ }^{1}\) A time series is a sequence of data points that occur in successive order over some period of time.
}
(Walpole,1982, page 346). This prediction is in the form of an expected value: \(\hat{y}=E\left(Y \mid x_{1}, \ldots, x_{n}\right)=\Psi\left(x_{1}, \ldots, x_{i}, \ldots, x_{n}\right)\)
where
\[
\begin{array}{ll}
\begin{array}{l}
\mathrm{Y} \\
\hat{y}
\end{array} & \begin{array}{l}
\text { : response or dependent variable } \\
x_{i}, i=1, \ldots, r
\end{array} \\
\begin{array}{l}
\text { :predicted value for } \mathrm{Y} \text { given } x_{1}, \ldots, x_{n} \\
\text { :independent variables }
\end{array} \\
& \\
\text { e.g.: }
\end{array}
\]

If \(\Psi\) is a linear function of \(x_{i}, i=1, \ldots, n\), the regression model is called linear regression which could be simple or multiple.

\section*{6-4-1-1Simple Linear Regression Model}

Simple linear regression is a linear regression model with a single independent (explanatory) variable and one dependent variable., denoted by X, Y respectively. The mathematical model of simple linear regression is as follows:
\[
\begin{equation*}
Y=a+b X+e \tag{6-1}
\end{equation*}
\]

Where a and b are the regression coefficients ,
\(e\) is the error variable with mean zero .
Given a particular value of X , taking expectation on both sides of Eq. (6.1), yields : \(E(Y)=a+b x+E(e)\). Then we have:
\[
\begin{equation*}
\mu_{Y / x}=E(Y / X=x)=a+b x \tag{6-2}
\end{equation*}
\]

The mean \(\mu_{Y / x}\) is considered a predicted value for Y when \(\mathrm{X}=\mathrm{x}\). The predicted value is denoted in this chapter by \(\hat{y}\) :
\[
\begin{equation*}
\hat{y}=a+b x \tag{6-3}
\end{equation*}
\]

\section*{6-4-1-1-1Estimation of model parameters with the method of Least squares}

In this section the regression coefficients \(a\) and \(b\) are estimated with a method often called least squares . in this method the sum of the squares of the residuals (the difference between results obtained by observation and by computation from a formula) is minimized. Given \(\left(x_{1}, y_{1}\right), \ldots,\left(x_{i}, y_{i}\right), \ldots,\left(x_{n}, y_{n}\right), \mathrm{n}\) pairs of values from the independent and dependent variables X and Y , we would like to estimate a and b in such away that \(\left(\hat{\mathrm{y}}_{\mathrm{i}}, \mathrm{y}_{\mathrm{i}}\right)\) i.e. the observed and predicted values for Y become close to each other as much as possible. In other words th aim in estimiating a and bis to minimized the errors e about the regression line (Fig 6-2).

Fig. 6-2 The predicted values ( \(\hat{y}\) ), the observed values(y) and the error(e) in simple regression.

To satisfy this requirement, the sum of the squares of the errors(SSE) about the regression line is usually mininimized i.e. the aim is to minimize:
\[
\begin{align*}
& S S E=\sum_{i=1}^{n} e_{i}^{2}=\sum_{i=1}^{n}\left(y_{i}-\hat{y}_{i}\right)^{2}(\mathbf{6}-\mathbf{4}) \\
& \text { SSE }==\sum_{i=1}^{n}\left(y_{i}-a-b x_{i}\right)^{2} \\
& \partial \mathrm{SSE} / \partial \mathrm{a}=0 \\
& \partial \mathrm{SSE} / \partial \mathrm{b}=0====> \\
& \hat{b}=\frac{\sum_{i=1}^{n} x_{i} y_{i}-\frac{1}{n} \sum_{i=1}^{n} x_{i} \sum_{i=1}^{n} y_{i}}{\sum_{i=1}^{n} x_{i}{ }^{2}-\frac{1}{n}\left(\sum_{i=1}^{n} x_{i}\right)^{2}}=\frac{S_{X Y}}{S_{X X}},  \tag{6-5}\\
& \hat{a}=\frac{\sum_{i=1}^{n} y_{i}-\hat{b} \sum_{i=1}^{n} x_{i}}{n}=\bar{Y}-\hat{b} \bar{X}, \tag{6-6}
\end{align*}
\]

Where
\(\bar{Y}\) is the mean of the oberved values \(y_{1}, \ldots, y_{n}\)
\(\bar{X}\) is the mean of the oberved values \(x_{1}, \ldots, x_{n}\).
The line \(\hat{y}=\hat{a}+\hat{b x}\) is called the line of least squared.

\section*{Example 6-1}

Estimate the regression line for the data of given in the following table
\begin{tabular}{|c|c|c|c|}
\hline X & Y & \(x^{2}\) & xy \\
\hline 77 & 5.5 & 5929 & 423.5 \\
\hline 75 & 5 & 5625 & 375 \\
\hline 72 & 4.7 & 5184 & 338.4 \\
\hline 71 & 4.8 & 5041 & 340.8 \\
\hline 70 & 4.6 & 4900 & 322 \\
\hline\(\sum x=365\) & \(\sum y=24.6\) & \(\sum x^{2}=26679\) & \(\sum x y=1799.7\) \\
\hline
\end{tabular}

\section*{Solution}

Using Eqs. 6-5 , 6-6 and the calcualtion done in the table:
\(\hat{b}=\frac{(5)(1799.7)-(365)(24.6)}{5(26679)-365^{2}}=0.1147 \quad \hat{a}=\frac{24.6-\hat{b}(365)}{5}=-3.453\)
Following MATLAB commands give similar results:
```

>> x=[[77 75 72 72 71 70]'; y=[[5.5 5 4.7 4.8 4.6]';
>> X = [ones(size(x)) x];
>>ab= regress(y,X) }\mp@subsup{}{}{1

```
-3.4535 0.1147
\({ }^{1} \mathrm{X}\) ly could be used instead of regress

The difference between the values obtained for a from Eq. 6-6 and MATLAB is due to the approximations used in the manual calculations.

The equation for the regression line is \(\hat{y}=-3.4531+.1147 x\). If the value of the independent variable for Period 6 is \(x_{6}=73\) then the dependendent variable fof the period is predicted to be on the average \(: \hat{y}_{6}=(.1147)(73)-3.4531=4.92\)

\section*{6-4-1-1-2 Correlation coefficient}

What makes simple linear regression appropriate for predicting Y from X is their degree of their linearity relation. The correlation coefficient is the specific measure that quantifies the strength of the linear relationship between two variables. Suppose a sample \(n\) pairs of X and Y are available; then the coefficient (r) is defined as follows:
\[
\begin{equation*}
\mathrm{r}=\frac{\mathrm{n} \sum \mathrm{x}_{\mathrm{i}} \mathrm{y}_{\mathrm{i}}-\left(\sum \mathrm{x}_{\mathrm{i}}\right)\left(\sum \mathrm{y}_{\mathrm{i}}\right)}{\sqrt{\mathrm{n} \sum \mathrm{x}_{\mathrm{i}}{ }^{2}-\left(\sum \mathrm{x}_{\mathrm{i}}\right)^{2}} \sqrt{\mathrm{n} \sum \mathrm{y}_{\mathrm{i}}{ }^{2}-\left(\sum \mathrm{y}_{\mathrm{i}}\right)^{2}}} . \tag{6-8}
\end{equation*}
\]

It is proved that \(-1 \leq r \leq 1\) and the more|r| closer to 1 the stronger the linear relation; and the more \(|r|\) closer to zero the weaker the linear relation. Negative \(r\) denotes that if \(x\) increases(decrease) Y will decrease (increase). Table 6-1 shows the relation between \(r\) and the degree of linear ity.
\begin{tabular}{|c|l|l|l|l|l|}
\hline \multicolumn{6}{|c|}{ Table 6-1 A classification of correlation of coefficient } \\
\hline\(|r|\) & \(0-0.2\) & \(0.2-0.4\) & \(0.4-0.7\) & \(0.7-0.9\) & \(0.9-1\) \\
\hline linearity & slight & weak & medium & satisfactory & high \\
\hline
\end{tabular}

As an example if we calculate the correlation coefficient of X, Y in Example 6-1, we will obtain \(\mathrm{r}_{\mathrm{xy}}=0.94\) which denotes that there is a strong linear relationship between X and Y . Figures 6-3 through 6-6 shows the linear strength of several sets of data. It is worth mentioning that such plots are which are
called scatter plot are necessary to understand the kind of relationship between 2 variables. It is desirable to have at least 30 pairs of data(Kume, 1992 page 68) to prepare a scatter plot in order to study the relation between X and Y .

Fig. 6-4 A Scatter plot of a set of data with low positive \(r\)

Fig. 6-5 A Scatter plot of a set of data with negative \(r\)

Fig. 6-4 Observed and predicted Fig. 6-5 A Scatter plot of a set data with high positive \(r\)
 of data with nearly zero \(r\)

\section*{6-5 Measures of Model Effectiveness}

To verify the validation of foreecating model, there are some measures including the ones given in Table 6-2 . In fact the formlus in Table 6-2 measures the forecasting error. It is
advised not to use a small set of data to estimate the parameters of the model and valdiating the model.
\begin{tabular}{|c|c|c|c|c|}
\hline Measure & Formula & Abb. & Measure & comment \\
\hline \begin{tabular}{l}
Mean \\
Between \\
Deviation
\end{tabular} & \[
\frac{\sum_{i=1}^{n}\left(y_{i}-\hat{y}_{i}\right)}{n}
\] & MBE & \begin{tabular}{l}
Mean \\
Between \\
Deviation
\end{tabular} & -Negative MBD: Prediction is greater than actual -Negative MBD: Prediction is less than
actual \\
\hline \begin{tabular}{l}
Mean \\
Absolute Deviation
\end{tabular} & \[
\sum_{i=1}^{n}\left|y_{i}-\hat{y}_{i}\right|
\] & \begin{tabular}{l}
MAD, \\
MAE
\end{tabular} & \begin{tabular}{l}
Mean \\
Absolute \\
Deviation
\end{tabular} & \\
\hline Mean Squared Errors & \[
\frac{\sum_{i=1}^{n}\left(y_{i}-\hat{y}_{i}\right)^{2}}{n}
\] & MSE & Mean Squared Errors & \\
\hline \begin{tabular}{l}
Root \\
Mean Squared
\end{tabular} & \(\sqrt{\frac{\sum_{i=1}^{n}\left(y_{i}-\hat{y}_{i}\right)^{2}}{n}}\) & RMSE & Root Mean Squared Errors & \\
\hline Standard Error of Estimate & \(\sqrt{\frac{\sum_{i=1}^{n}\left(y_{i}-\hat{y}_{i}\right)^{2}}{n-f}}\) & SEE & Standard Error of Estimate & \(f\) is the number parameters to be e4stimated for the Forecaster equation \\
\hline \begin{tabular}{l}
Mean \\
Absolute \\
Percentage \\
Error
\end{tabular} & \[
\frac{100}{\mathrm{n}} \sum_{i=1}^{n}\left|\frac{y_{i}-\hat{y}_{i}}{y_{i}}\right|
\] & MAPE & \begin{tabular}{l}
Mean \\
Absolute \\
Percentage \\
Error
\end{tabular} & Gives a dimensionless Measure for error \\
\hline
\end{tabular}

The corelation coefficient (R)between the obseved ( \(y_{i}\) ) and predicted \(\left(\hat{y}_{i}\right)\) values from the following relationship is sometimes used in the literature .
\[
\begin{equation*}
R=\frac{n \sum y_{i} \hat{y}_{i}-\left(\sum y_{i}\right)\left(\sum \hat{y}_{i}\right)}{\sqrt{n \sum y_{i}^{2}-\left(\sum y_{i}\right)^{2}} \sqrt{n \sum \hat{y}_{i}^{2}-\left(\sum \hat{y}_{i}\right)^{2}}} \tag{6-9}
\end{equation*}
\]

However high R does not necessarily indicate that the prdicted values are appropriate. If R is used another measure such as RMSE has to accompany the coreelation coefficient.

Some researches use a statistic called the Coefficient of determination, denoted by \(R^{2}\left(0 \leq R^{2} \leq 1\right)\),to judge the adequacy of a regression model. However the statistic has several miscionceptions (Montgomery and Rungers, page 510) .

Three other measures of model adequacy are:the coefficient of multiple determination, residual analysis, testing lack of fit using near neighbors. For details refer to Hines\& Montgomeri(1990) chapter 15 page 505.

\section*{5-6-1 Application of 't-test for paired data" to model effici study}

To study the effectve ness of a forecating model, if the difference (D)of the obseved values and the corresponding predicted values are normally distributed, a special \(t\)-test could be used to test;
\[
\begin{aligned}
& H_{0}: \mu_{D}=0 \\
& H_{1}: \mu_{D} \neq 0
\end{aligned} .
\]

The test statistic under null hypothes is (Bowker and lieberman, 1972 page243):
\[
\begin{equation*}
t_{0}=\sqrt{\frac{n \bar{D}^{2}}{S_{D}^{2}}} \tag{6-10}
\end{equation*}
\]

Where
\[
\begin{aligned}
& \bar{D}=\sqrt{\frac{\sum_{i=1}^{n} D_{i}}{n}}=M B D \\
& S_{D}=\sqrt{\frac{\sum_{i}^{2}-n \bar{D}^{2}}{n-1}} .
\end{aligned}
\]

The test statistic could be calculated equivalently from
\[
\begin{equation*}
t_{0}=\sqrt{\frac{(n-1) M B D^{2}}{R M S E^{2}-M B D^{2}}} \tag{6-11}
\end{equation*}
\]

Where
\[
R M S E=\sqrt{\frac{\sum_{i=1}^{n}\left(y_{i}-\hat{y}_{i}\right)^{2}}{n}}=\sqrt{\frac{\sum_{i=1}^{n} D_{i}^{2}}{n}} .
\]

Eqs 6-10\& 6-11 are equivalent because:
\(t_{0}=\sqrt{\frac{n \bar{D}^{2}}{S_{D}^{2}}}=\sqrt{\frac{n \bar{D}^{2}}{\frac{\sum D_{i}^{2}-n \bar{D}^{2}}{n-1}}}=\sqrt{\frac{(n-1) \bar{D}^{2}}{\frac{\sum D_{i}^{2}-n \bar{D}^{2}}{n}}}=\)
\(\sqrt{\frac{(n-1) \bar{D}^{2}}{\frac{\sum D_{i}^{2}}{n}-\bar{D}^{2}}}=\sqrt{\frac{(n-1) M B D^{2}}{R M S E^{2}-M B D^{2}}}\).
If \(t_{0}\) is not greater than the critical value \(t_{n-1, \alpha / 2}\), then the mean of the observed values \(\left(y_{i} ' s\right)\) and the mean of the predicted values ( \(\hat{y}_{i}\) 's) doenot differ significantly.

\section*{6-6 Multiple Linear Regression}

When we have a case in which one variable depends on several independent variables, multiple regression models which is specific- ally designed to create regressions for such cases may be a good choice. The multiple linear regression with k independent variables (regressors) is represented by (Montgomeri\&rungers,1994page 533):
\[
\begin{equation*}
Y=a+b_{1} X_{1}+b_{2} X_{2}+\ldots+b_{k} X_{k}+e \tag{6-12}
\end{equation*}
\]
where
\begin{tabular}{|l|l|}
\hline\(Y\) & dependent variable \\
\hline\(X_{1}, X_{2}, \ldots, X_{k}\) & independent variables \\
\hline\(b_{k}, \ldots, b_{2}, b_{1}, a\) & model parameters \\
\hline\(e\) & error random variable with mean zero \\
\hline
\end{tabular}

Given some specific values for \(X_{1}, X_{2}, \ldots, X_{k}\), we could take the expection of both sides of Eq. 6-12 as follows:
\[
\hat{y}=E\left(Y \mid X_{1}=x_{1}, \ldots, X_{k}=x_{k}\right)=a+b_{1} x_{1}+b_{2} x_{2}+\ldots+b_{k} x_{k}+E(e)
\]

Since \(\mathrm{E}(\mathrm{e})=0\) then Given \(\quad X_{1}=x_{1}, X_{2}=x_{2}, \ldots, X_{k}=x_{k}\), the predicted value for the dependent variable \((\hat{y})\) iscalculated from:
\[
\begin{equation*}
\hat{y}=a+b_{1} x_{1}+b_{2} x_{2}+\ldots+b_{k} x_{k} . \tag{6-13}
\end{equation*}
\]

Estimation of the model parameters by the help of has been dealt in refrences such as Montomeri\&Rungers(1994) and softwares such as such as MATLAB and Minitab. The following commands might be used in MATLAB to estmate the k-regressor linear model paramters:
\[
\begin{aligned}
& x_{1}=[\ldots \ldots . .]^{\prime} ; x_{2}=[\ldots \ldots . .]^{\prime} ; x_{k}=[\ldots \ldots . .]^{\prime} ; y=[\ldots \ldots . .]^{\prime} \\
& \gg \mathrm{X}=[\operatorname{ones}(\operatorname{size}(\mathrm{x} 1)) \mathrm{x} 1 \mathrm{x} 2 \ldots \mathrm{xk}] ; \operatorname{regress}(\mathrm{y}, \mathrm{X}) \text { or } \mathrm{X} \backslash \mathrm{y} .
\end{aligned}
\]

Hines ant Montgomeri () on page 502 mentions that adding an unimportant variable to the model can actually increase the mean square error(MSE), thereby decrease the usefulness of the model. Note that the relations of the form \(y=\beta_{0} x_{1}^{\beta_{1}} \times \ldots \times x_{k}^{\beta_{k}}\) could be transformed to \(\log y=\log \beta_{0}+\beta_{1} \log x_{1}+\ldots+\beta_{k} \log x_{k}\) and by setting \(\log x_{i}\) 's equal to a new variable, a linear regression model is achieved.

\section*{Example 6-2}

The following table shows the results of an experiment . Without performing an experiment, could we forecast the result of the experiment if the values of \(X_{1}\) and \(X_{2}\) are given.
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline \(\mathrm{x}_{1}\) & 1.10 & 1.00 & 0.80 & 0.60 & 0.50 & 0.20 \\
\hline \(\mathrm{x}_{2}\) & 1.40 & 1.10 & 0.90 & 0.400 & 0.30 & 0.10 \\
\hline y & 0.24 & 0.27 & 0.23 & 0.28 & 0.26 & 0.17 \\
\hline
\end{tabular}

\section*{Solution}

To see if a double linear regression model fits the data or not, at first the parametrs are estimated:

\(\mathrm{X}=[\) ones(size(x1)) x1 x2 \(]\);
>> regress(y,X)
\(0.1018 \quad 0.4844 \quad-0.2847\)
The model is \(\hat{y}=0.1018+0.4844 \times 1-0.2847 \times 2\)
We do not have any other data for model validation, therefore the above data are inserted in the model as follows:
yhat \(=0.1018+0.4844 * x 1-0.2847 * x 2\) or
\(\hat{\mathrm{y}}=\left[\begin{array}{lll}\mathrm{ones}(6,1) & \mathrm{x}_{1} & \mathrm{x}_{2}\end{array}\right]^{*}\left[\begin{array}{lll}0.1018 & 0.4844-0.2847\end{array}\right]^{\prime}\)
The results are given in the following table:
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline y & 0.17 & 0.26 & 0.28 & 0.23 & 0.27 & 0.24 \\
\hline\(\hat{\mathrm{y}}\) & 0.1702 & 0.2586 & 0.2786 & 0.2331 & 0.2730 & 0.2361 \\
\hline
\end{tabular}

The correlation coefficient between the observed and predicted values is \(R=0.9976\) calculated in MATLAB as follows:M=corrcoef(y, yhat);R=M(1,2).

With RMSE \(=0.0025\) calculated in MATLAB by rmse=sqrt(mse(y-yhat)).

Before closing this section, a summary of Saffaripour et \(\mathrm{al}(2013)\) is mentioned below:

The purpose of this investigation is to develop statistical models to estimate the mean daily global solar radiation flux, H, using multiple linear regression models.

The mean daily global solar radiation flux is influenced by astronomical, climatological, geographical, geometrical, meteorological, and physical parameters. This paper deals with the study of the effects of influencing parameters on the mean daily global solar radiation flux.

Saffaripour et al(2013) used multiple linear regression of several parameters in different combinations. The models gave many different correlations to estimate the global solar radiation
fluxes. For example one of the linear regression models they developed was the following relationship:
\(\hat{H}=-17082.9+619.68 \sin \delta+0.59 H_{0}+3277.15 n / N\)
\(+24.34 R_{h}+64.78 T_{\text {max }}+104.25 T_{d p(\text { max })}+14.64 P\)
where
\(\hat{H} \quad\) Predicted value for the mean daily global solar radiation flux
\(\delta \quad\) the solar declination angle
\(\mathrm{H}_{0} \quad\) The extraterrestrial solar radiation flux
n Hours of measured sunshine
\(N \quad\) the maximum possible sunshine hours from sunrise to sunset
\(\mathrm{n} / \mathrm{N} \quad\) sunshine duration ratio
\(R_{h} \quad\) mean daily relative humidity
\(T_{\text {max }} \quad\) mean daily maximum air temperature
\(\mathrm{T}_{\text {dp(max) }} \quad\) mean daily maximum dew point temperature
P
mean daily atmospheric pressure
The following table shows the value for the mean daily global solar radiation flux predicted from the above model \((\widehat{H})\) and the actual mean values \((\bar{H})\).
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|l|l|}
\hline & Jan & Feb & Mar & Apr & May & Jun & Jul & Aug & Sep & Oct & Nov & Dec \\
\hline \(\bar{H}\) & 3583 & 4602 & 5358 & 6473 & 7491 & 8192 & 7956 & 7656 & 6827 & 5440 & 4050 & 3421 \\
\hline\(\widehat{H}\) & 3630 & 4813 & 5267 & 6457 & 7485 & 8257 & 7999 & 7511 & 6823 & 5611 & 3907 & 3308 \\
\hline
\end{tabular}

Saffaripour et al(2013) calculated the correlation coefficient related to each of the models they created and carried a t-test to choose the appropriate model(s).

The above model could be used to predict daily global solar radiation flux \((\mathrm{H})\) from atmospheric pressure, air temperature, etc... when the expensive instrument which is used to measure H is not available.

\section*{Classical time series forecasting methods}

This section introduces some models that are used to predict the future from past data in the form of time series. Some of the models that are used for time series analysis are:

Arithmetic average, simple moving average(MA),weighted moving average, exponential smoothing(single, double, triple), regression, time series decomposition. Decomposition method that splits a time series into several components is suitable for a set of, time series containing seasonal variation. The application of some methods for time series analysis have been shown in Table 6-3 with the help of scatter plots.

Table 6.3 Application of forecasting methods(Dilworth, 1989 page 131)
APPLICATION OF FORECASTING METHODS
\begin{tabular}{|c|c|c|}
\hline Combination of Components in the Series & Objectives & Models Often Appropriate \\

\hline
\end{tabular}
-If the scries of demand data shows a generally consistent pattern over time and the influencing
conditions are expected to continue, a time series model often is adequate. then causal models should be investig
Not discussed in detail in this chapter.

\section*{6-7 Simple Moving Average(SMA)}

Moving average method in its simplest form calculates the forecast for the coming next period by adding up the latest " N " period's observed data and dividing the sum by N as follows:
\[
\begin{equation*}
\hat{y}_{t+1}=\frac{\sum_{i=t}^{t+1-N} y_{i}}{N} \tag{6-14}
\end{equation*}
\]
where
\(\hat{y}_{t+1}\) is the forecast for Period " \(t+1\) " and
\(y_{i}\) is the \(\mathrm{i}^{\text {th }}\) observed value"

For example if the data for the past five periods are \(y=\left[\begin{array}{lllll}5.5 & 5.0 & 4.7 & 4.8 & 4.6\end{array}\right]\), The forecast for Period 6 according to SMA would be:
\(\hat{y}_{6}=\frac{4.6+4.8+4.7}{3}=4.7\).

If there is no considerable trend or no considerable seasonal variation, SMA gives an appropriate result. If the N is small random variations affects forecast. Large N smoothes random variations

The larger the value of N (period of moving average), the smaller is the effect of random variation and \(a\) higher smoothing effect. The value of N depends upon the speed at which the pattern of demand changes. If the The pattern is not stable, a small value of N should be selected (Telsang \({ }^{1}, 1998\) page 526). If the variation of the demand over time is considerable choose a small N (e.g. 3,4,5) ; if it is small choose \(12 \leq N \leq 18\) ( Hajji,2012 page 173) .
\({ }^{1}\) Telsang, M. T , 1998, Industrial Eng;g and Production Manag, S Chand And Co. Ltd

To find the appropriate N for a given case, a short computer code might be prepared to find the N with minimum error. Needless to say that finding an appropriate N for moving average( MA) method does not imply that MA is the most suitable method. As an illustration consider the following 20period time series:
```

1.5563
0 0 -0.0969 -0.2218

```

To find the appropriate N for using MA method, a simple computer code gives RMSE for several periods of moving range method ( N ) as follows:
\begin{tabular}{|l|l|l|l|}
\hline \multicolumn{3}{|c|}{ Table 6-4 RMSE for several N } \\
\hline N & RMSE & N & RMSE \\
\hline 1 & 0.1076 & 9 & 0.1095 \\
\hline 2 & 0.3167 & 10 & 0.0962 \\
\hline 3 & 0.2703 & 11 & 0.0732 \\
\hline 4 & 0.2271 & 12 & 0.0444 \\
\hline 5 & 0.1900 & 13 & 0.0260 \\
\hline 6 & 0.1597 & \(\mathbf{1 4}\) & \(\mathbf{0 . 0 0 8 2}\) \\
\hline 7 & 0.1368 & 15 & 0.0116 \\
\hline 8 & 0.1231 & 16 & 0.0273 \\
\hline
\end{tabular}

Table 6-4 suggests to choose \(\mathrm{N}=14\). Using this N the predicted value for the following observed value \(y_{17}=-0.2218 \quad y_{18}=-0.3979 \quad y_{19}=-0.5229 \quad y_{20}=-0.0458\)

Are:
\(\hat{y}_{17}=-0.2582 \quad \hat{y}_{18}=-0.2582 \quad \hat{y}_{19}=-0.2582 \quad \hat{y}_{20}=-0.2582\),

\section*{6-8 Modified Moving Average}

In modified moving range method, The value for Period K from now \(\left(\hat{y}_{t+k}^{\prime}\right)\) could be forecasted using the following relationship:
\[
\begin{equation*}
\hat{y}_{t+k}^{\prime}=\hat{y}_{t}+k b \tag{6-15}
\end{equation*}
\]

Where
\[
\begin{aligned}
& \hat{y}_{t}=A_{t}+\frac{6 s}{N(N+1)} \quad A_{t}=\frac{\sum_{i=t-N+1}^{t} y_{i}}{N} \quad b=\frac{12 s}{N\left(N^{2}-1\right)} \\
& \mathrm{s}=\frac{\mathrm{N}-1}{2} \mathrm{y}_{\mathrm{t}}+\frac{\mathrm{N}-3}{2} \mathrm{y}_{\mathrm{t}-1}+\frac{\mathrm{N}-5}{2} \mathrm{y}_{\mathrm{t}-2}+\frac{\mathrm{N}-7}{2} \mathrm{y}_{\mathrm{t}-3}+\ldots+\frac{\mathrm{N}-(2 \mathrm{~N}-1)}{2} \mathrm{y}_{\mathrm{t}-\mathrm{N}+1}= \\
& \frac{\mathrm{N}-1}{2} \mathrm{y}_{\mathrm{t}}+\frac{\mathrm{N}-3}{2} \mathrm{y}_{\mathrm{t}-1}+\ldots-\frac{\mathrm{N}-3}{2} \mathrm{y}_{\mathrm{t}-\mathrm{N}+3}-\frac{\mathrm{N}-1}{2} \mathrm{y}_{\mathrm{t}-\mathrm{N}+1}
\end{aligned}
\]

Note that in fact \(A_{t}\) is the forecast for Period \(\mathrm{t}+1\) dy simple moving Average(MA) method.

The total sum of the forecasted values for Periods \(t+1\) through \(\mathrm{t}+\mathrm{L}\) is given by:
\[
\begin{gather*}
\text { forecasts sum for }  \tag{6-16}\\
\text { Periods } t+1 \text { through } t+\mathrm{L}
\end{gather*}=L \hat{y}_{t}+\frac{L(L+1) b}{2}
\]

\section*{Example 6-3}

The actual demands for January through June are given in the following table:
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline Period \((t)\) & Jan & Feb & Mar & Apr & May & Jun \\
\hline demand & 90 & 50 & 80 & 64 & 75 & 70 \\
\hline
\end{tabular}

Find the forecasts for July and August using 6- period MA technique and also calculate the total sum of the forecasted values for Periods July through September.

\section*{Solution}
\[
\begin{aligned}
& \hat{y}_{7}^{\prime}=\hat{y}_{6}+b \quad \hat{y}_{6}=A_{6}+\frac{6 s}{N(N+1)} \\
& s=(6-1)(70) / 2+(6-3)(75) / 2+(6-5)(64) / 2 \\
& +(6-7)(80) / 2+(6-9)(5) / 2+(6-11)(90) / 2=20.5 \\
& A_{6}=(90+50+80+64+75+70) / 6=71.5 \quad b=\frac{12(20.5)}{6\left(6^{2}-1\right)}=1.17 \\
& \hat{\mathrm{y}}_{6}=71.5+\frac{6(20.5)}{6(7)}=74.36, \hat{y}_{7}^{\prime}=\hat{\mathrm{y}}_{6}+\mathrm{b}=74.36+1.17=75.53 . \\
& \hat{y}_{8}^{\prime}=\hat{y}_{6}+2 b=74.36+2 \times 1.17=76.70 .
\end{aligned}
\]

Total sum of forecasts for Periods July through September \(=3 \hat{y}_{6}+\frac{3(3+1)}{2} \times 1.17=230.11\)

\section*{6-9 Weighted Moving Average}

In simple moving average equal weights were assigned to all N periods; However some- times it is required to assign heavier weighting to more recent data points. This causes the more current data to have heavier effect on the forecast value than the older data. If there is a trend in data, to choose between the weighted moving average(MA) and simple MA, choose the weighted MA.

\section*{Weighted moving average(WMA) formula}

Mathematically in WMA method the forecast is computed from either of the following formula, depending on the sum of the assigned weights ( \({ }^{w_{t}}\) 's):
\[
\begin{gather*}
\hat{y}_{t+1}=w_{t} y_{t}+w_{t-1} y_{t-1}+\ldots+w_{t-N+1} y_{t-N+1}, \quad \sum w=1 . \quad(6-17) \\
\hat{y}_{t+1}=\frac{\sum_{i=t+1-k}^{N} w_{i} y_{i}}{\sum_{i=t+1-k}^{N} w_{i}} \tag{6-18}
\end{gather*}
\]

\section*{Example 6-3}

Suppose the demand for a product from period 1 to 5 are 8, \(12,14,18,22\) find the forecast for period 6 assigning the weight 0.8 for Period 5 and 0.2 for Period 4.

\section*{Solution}

From Eq. \(\quad 6-17: \quad \hat{y}_{6}=0.8 \times 22+0.2 \times 18=21.2\)

\section*{6-10 Exponential Smoothing}

Exponential smoothing which is sometimes called Exponentially weighted moving average, developed by Holt(1957), is actually a weighted MA with a fairly easy to use formula. Practically it uses very little of the past data record. Holt's primary approach did not consider trend and seasonality; however, later he introduced trend in the model. Winters (1960) extended the model for reasonability.

The basic exponential smoothing uses the following formula:
\[
\begin{equation*}
\hat{y}_{t+1}=\hat{y}_{t}+\alpha\left(y_{t}-\hat{y}_{t}\right)=\alpha y_{t}+(1-\alpha) \hat{y}_{t} \tag{6-19}
\end{equation*}
\]

Where
\(\hat{y}_{t+1} \quad\) New forecast
\(\hat{y}_{t} \quad\) Last period's forecast
\(y_{t} \quad\) Last period's actual demand
\(\alpha \quad\) A smoothing constant that lies between 0 and 1 often
\(0.1<\alpha<0.5\) and in practice is usually chosen equal to 0.1 , 0.3 or 0.5 (Winston, 1994, page 1262)

More details about the above formula could be found in references such as Johnson \& Montgomeri(1974)

The appropriate \(\alpha\) for a particular case could be found by a computer code which minimizes a forecast error measure like MAD or RSME

As said before exponential smoothing is in essence a weighted MA. As we move backward the weighting and importance of the data points decreases depending on the value of \(\alpha\).

To forecast the next period demand( \(\mathrm{t}+\) !), the use of exponential smoothing, requires an initial forecast for current Period t . A common initial forecast is the arithmetic average of the past data up to the current Period (Housyar,1985). If we have a largish record of data the initial forecast could be replaced by \(\hat{y}_{n+1}=\alpha{ }_{i=0}^{i=n-1}(1-\alpha)^{i} y_{n-i}\). The reason for this will be shown soon.

\section*{Example 6-4}

Using the data in the following table, find the forecast for Period 7 with simple exponential smoothing.
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline t & 1 & 2 & 3 & 4 & 5 & 6 \\
\hline y & 30 & 32 & 30 & 39 & 33 & 34 \\
\hline
\end{tabular}

\section*{Solution}
\[
\begin{aligned}
& \hat{y}_{7}=0.1 y_{6}+(1-0.1) \hat{y}_{6} \hat{y}_{6}=\frac{34+\ldots+30}{6}=33 \\
& \hat{y}_{7}=0.1 y_{6}+(1-0.1) \hat{y}_{6}=33.1 \mathbf{\Delta}
\end{aligned}
\]

Notice that this was an exercise. The utilized method is not necessarily the best method for the case .

As the following calculations shows, in exponential smoothing the weightings assigned to the data points decreases as the data get older
\[
\begin{aligned}
\hat{\mathrm{y}}_{\mathrm{t}+1} & =\alpha \mathrm{y}_{\mathrm{t}}+(1-\alpha) \hat{\mathrm{y}}_{\mathrm{t}}=\alpha \mathrm{y}_{\mathrm{t}}+(1-\alpha)\left[\alpha \mathrm{y}_{\mathrm{t}-1}+(1-\alpha) \hat{\mathrm{y}}_{\mathrm{t}-1}\right] \\
& =\alpha \mathrm{y}_{\mathrm{t}}+\alpha(1-\alpha) \mathrm{y}_{\mathrm{t}-1}+(1-\alpha)^{2} \hat{\mathrm{y}}_{\mathrm{t}-1}
\end{aligned}
\]

Then
\[
\begin{aligned}
\hat{\mathrm{y}}_{\mathrm{t}+1} & =\alpha \mathrm{y}_{\mathrm{t}}+\alpha(1-\alpha) \mathrm{y}_{\mathrm{t}-1}+\alpha(1-\alpha)^{2} \mathrm{y}_{\mathrm{t}-2}+\ldots+\alpha(1-\alpha)^{\mathrm{k}} \mathrm{y}_{\mathrm{t}-\mathrm{k}} \\
& +\ldots+\alpha(1-\alpha)^{t-1} \mathrm{y}_{1}+(1-\alpha)^{\mathrm{t}} \hat{\mathrm{y}}_{1} \Rightarrow \\
& \hat{\mathrm{y}}_{\mathrm{t}+1}=\alpha \sum_{\mathrm{i}=0}^{\mathrm{i}=\mathrm{t}-1}(1-\alpha)^{\mathrm{i}} \mathrm{y}_{\mathrm{t}-\mathrm{i}}+(1-\alpha)^{\mathrm{t}} \hat{\mathrm{y}}_{1}
\end{aligned}
\]

If the number terms is largish \((t \rightarrow \infty),(1-\alpha)^{t} \hat{y}_{1} \stackrel{\text { zero and }}{ }\) then if \(t \rightarrow \infty, \quad \hat{\mathrm{y}}_{\mathrm{t}+1} \cong \alpha \sum_{\mathrm{i}=0}^{\mathrm{i}=t-1}(1-\alpha)^{\mathrm{i}} \mathrm{y}_{\mathrm{t}-\mathrm{i}}\). The sum of the coefficients in the first part approaches one:
\(\alpha(1-\alpha)^{0}+\alpha(1-\alpha)^{1}+\alpha(1-\alpha)^{2}+\ldots=\alpha\left[\frac{1}{1-(1-\alpha)}\right]=1\)
The above calculations shows if we proceed further backward as much as possible we will notice that the forecast resulted from exponential smoothing is a weighted average from all data. The weightings decrease exponentially(Fig. 6-8). Furthermore if \(n \rightarrow \infty\) i.e. we have a lot of information as past data ,then \(\hat{y}_{n+1} \cong \alpha \sum_{i=0}^{i=n-1}(1-\alpha)^{i} y_{n-i}\) could be used as the intitial forecast for using Eqs. 6-18 \& 6-19.

Fig. 6-8 The weightings in a simple exponential Smoothing with \(\alpha=0.25\).

The calculation in Table 6-5 shows small \(\alpha\) assingns greater weighting and importance to more recent data and less importance to older data.

Table 6-5 The values of some coefficient calculated for some \(\alpha\)
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline\(\alpha\) & \(\alpha\) & \(\alpha(1-\alpha)\) & \(\alpha(1-\alpha)^{2}\) & \(\cdots\) & \(\alpha(1-\alpha)^{10}\) & \(\cdots\) \\
\hline\(\alpha=0.1\) & 0.1 & 0.09 & 0.081 & \(\cdots\) & 0.035 & \(\cdots\) \\
\hline\(\alpha=0.2\) & 0.2 & 0.16 & 0.128 & & 0.0215 & \\
\hline\(\alpha=0.3\) & 0.3 & 021 & 0.147 & \(\cdots\) & 0.009 & \(\cdots\) \\
\hline\(\alpha=0.5\) & 0.5 & 0.25 & 0.125 & & 0.0004 & \\
\hline
\end{tabular}

Smaller \(\alpha\) gives greater values to older data points than greater \(\alpha\) does

\section*{Example 6-5}

The second column from the left in Table 6-6' shows the observed values for 24 periods. Calculate the forecast for the periods using

Exponential smoothing with smoothing parameters \(\alpha=0.1\) and \(\alpha=0.2\). Which parameter do you prefer

Solution( Dilworth. 1989 page 111)
Columns 3 and 5 of Table 6-6' show the forecast using simple exponential smoothing method with \(\alpha=0.1\) and \(\alpha=0.2\) respectively.
Table 6-6' Forecasts for Example 6-5 using Exponential Smoothing with \(\alpha=0.1 \& 0.2\)
\begin{tabular}{|l|l|l|l|l|l|}
\hline t & \begin{tabular}{l} 
Observe \\
\(\mathrm{d}\left(y_{t}\right)\)
\end{tabular} & \begin{tabular}{l} 
Forecast \\
\(\left(\hat{y}_{t}, \alpha=0.1\right)\)
\end{tabular} & \begin{tabular}{l}

\hline 5 & 192 & 197.1118 & B & 197.3955 & B \\
\hline 6 & 186 & 196.6006 & 112.3727 & 196.3164 & 106.4 \\
\hline 7 & 190 & 195.5406 & 30.6982 & 194.2531 & 18.1 \\
\hline 8 & 208 & 194.9865 & 169.3512 & 193.4025 & 213.1 \\
\hline 9 & 190 & 196.2879 & 39.5377 & 196.3220 & 40 \\
\hline 10 & 220 & 195.6591 & 592.4794 & 195.0576 & 622.1 \\
\hline 11 & 223 & 198.0932 & 620.3487 & 200.0461 & 526.9 \\
\hline 12 & 175 & 200.5839 & 654.5359 & 204.6369 & 878.3 \\
\hline 13 & 205 & 198.0255 & 48.6437 & 198.7095 & 39.6 \\
\hline 14 & 178 & 198.7229 & 429.4386 & 199.9676 & 482.6 \\
\hline 15 & 214 & 196.6506 & 301.0017 & 195.5741 & 339.5 \\
\hline 16 & 181 & 198.3856 & 302.2591 & 199.2593 & 333.4 \\
\hline 17 & 187 & 196.6470 & 93.0646 & 195.6074 & 74.1 \\
\hline 18 & 217 & 195.6823 & 454.4443 & 193.8859 & 534.3 \\
\hline 19 & 184 & 197.8141 & 190.8294 & 198.5087 & 210.5 \\
\hline 20 & 196 & 196.4327 & 0.1872 & 195.6070 & 2 \\
\hline 21 & 202 & 196.3894 & 31.4788 & 195.6856 & 39.9 \\
\hline 22 & 169 & 196.9505 & 781.2305 & 196.9485 & 781.1 \\
\hline 23 & 223 & 194.1554 & 832.0109 & 191.3588 & 1001.2 \\
\hline 24 & 190 & 197.0399 & 49.5602 & 197.6870 & 59.1 \\
\hline & & & RMSE=17.37 & & RMSE=18 \\
\hline A & & & & \\
\hline
\end{tabular}

A Initial mean estimated prior to these calculations \(=196.2\)
\(B\) omitted to reduce the effect of the initial mean

RMSE for \(\alpha=0.1\) is 17.37 and RMSE for \(\alpha=0.2\) is 18.21 .
Therefore \(\alpha=0.1\) is preferable for this case.

\section*{6-10-1 Relation between simple moving average and simple exponential smoothing}

As you have noticed, in the above methods, the user has to specify a parameter: In simple moving aver, the number of periods \((\mathrm{N})\) must be set and in simple exponential smoothing , the smoothing parameter \((\boldsymbol{\alpha})\). In both cases the parameter determine the importance of fresh information over older information(Shemueli, et al 2010, page 352). It has been proved that the following relationship exits between N and \(\boldsymbol{\alpha}\) ( Brown, 1962):
\[
\begin{equation*}
N=\frac{2-\alpha}{\alpha} \tag{6-21}
\end{equation*}
\]

In other words,, an N-period approximately similar to those

MA method gives results of a simple exponential smoothing with
\[
\begin{equation*}
\alpha=\frac{2}{N+1}, \tag{6-22}
\end{equation*}
\]

\section*{6-11 Double Exponential Smoothing}

Simple Exponential Smoothing cannot forecast accurately when there is trend or seasonal variation in the data Double Exponential Smoothing extends Simple Exponential Smoothing to support analyzing data that shows a trend by adding a second equation with a second parameter to the procedure.

If the data involves a linear trend, there would be a time \(\operatorname{lag}(\mathrm{LT})\) equal to \(\mathrm{LT}=\frac{1-\alpha}{\alpha}\) between the forecast resulted from Simple Exponential Smoothing(SES) and the corresponding observed data. Double Exponential Smoothing corrects this lag by forecasting for the next period using the following formula:
\[
\begin{equation*}
\hat{y}_{t+1}^{\prime}=A_{t}^{\prime}+\bar{T}_{t} \tag{6-23}
\end{equation*}
\]

Where
\[
\begin{array}{ccc}
A_{t}^{\prime} & =A_{t}+\frac{1-\alpha}{\alpha} \bar{T}_{t} & \\
\mathrm{~A}_{\mathrm{t}} & =\alpha \mathrm{y}_{\mathrm{t}}+(1-\alpha) \mathrm{A}_{\mathrm{t}-1} & \begin{array}{l}
\text { The initial forecast using } \\
\text { SES i.e. } A_{t}=\hat{y}_{t+1}
\end{array} \\
\frac{1-\alpha}{\alpha} \bar{T}_{t} & & \begin{array}{l}
\text { The correction value to } \\
\text { compensate for the trend }
\end{array} \\
\bar{T}_{t} & =\overline{T_{t-1}+\beta\left(T_{t}-\bar{T}_{t-1}\right)} \begin{array}{cc}
=\beta T_{t}+(1-\beta) \bar{T}_{t-1} \\
T_{t} & =A_{t}-A_{t-1}
\end{array} \\
\beta & 0 \leq \beta \leq 1 &
\end{array}
\]

To forecast using double exponential smoothing, initial values \(\left(A_{0}, \overline{T_{0}}\right)\) are needed. A suitable value for \(A_{0}\) is the average of the past data. And a suitable value for \(\overline{T_{0}}\) is the average of the differences between 2 successive observed values.

Note that \(\alpha, \beta\) which are smoothing coefficients between 0 and 1 are not necessarily equal.

If the trend continues, the forecast for k periods from now in this method is:
\[
\begin{equation*}
\hat{y}_{t+k}^{\prime}=A '_{t}^{\prime}+k \overline{T_{t}}, \tag{6-24}
\end{equation*}
\]

And the sum of corrected forecasts for L period from now is:
\[
\begin{equation*}
\sum_{i=1}^{L} \hat{y}_{t+i}^{\prime}=L \times A_{t}^{\prime}+\frac{(L)(L+1)}{2} \overline{T_{t}} \tag{6-25}
\end{equation*}
\]

If the trend does not continues, the forecast for k periods from now in this method is:
\[
\begin{equation*}
\hat{y}_{t+k}^{\prime}=A_{t}^{\prime} . \tag{6-26}
\end{equation*}
\]

\section*{Example 6-6}

A factory uses exponential smoothing with trend adjustment . From past data we only know that . \(A_{0}=50\) ton \(\overline{T_{0}}=1\) ton If the actual demand for the current period is \(y_{1}=55\) ton and \(\alpha=\beta=0.1\) :

What is the forecast for the next period \((\mathrm{t}=2)\) ?
Fid the sum of forecast for the next coming 2 periods?

\section*{Solution}
a)
\[
\hat{y}_{1+1}^{\prime}=A^{\prime},+\bar{T}_{1},
\]
\[
\overline{\mathrm{T}}_{1}=0.1 \mathrm{~T}_{1}+(1-0.1) \overline{\mathrm{T}}_{0}=0.1 \mathrm{~T}_{1}+0.9 \overline{\mathrm{~T}}_{0}
\]
\[
\mathrm{T}_{1}=\mathrm{A}_{1}-\mathrm{A}_{0}=\mathrm{A}_{1}-50
\]
\[
\mathrm{A}_{1}=\alpha \mathrm{y}_{1}+(1-\alpha) \mathrm{A}_{0}=0.1 \times 55+0.9 \times 50=50.5 \Longrightarrow \mathrm{~T}_{1}=0.5 \quad \overline{\mathrm{~T}}_{1}=0.95
\]
\[
\mathrm{A}_{1}^{\prime}=\mathrm{A}_{1}+\frac{1-\alpha}{\alpha} \overline{\mathrm{T}}_{1}=50.5+\frac{1-0.1}{0.1} \times .95=59.5
\]
\[
\hat{\mathrm{y}}_{2}^{\prime}=\mathrm{A}_{1}^{\prime}+\overline{\mathrm{T}}_{1}=59.5+0.95=60.45
\]
b)

The sum of the forecasts is :
\[
\begin{aligned}
& \sum_{\mathrm{i}=1}^{\mathrm{L}} \hat{\mathrm{y}}_{\mathrm{t}+\mathrm{i}}^{\prime}=\mathrm{L} \times \mathrm{A}_{\mathrm{t}}^{\prime}+\frac{(\mathrm{L})(\mathrm{L}+1)}{2} \overline{\mathrm{~T}}_{\mathrm{t}}=2 \mathrm{~A}_{1}^{\prime}+\frac{(2)(2+1)}{2} \\
&=2 \times 59.5+3 \times .95=120.95 \quad \text { or } \\
& \hat{\mathrm{T}}_{1} \\
& \hat{\mathrm{y}}_{2}^{\prime}+\hat{\mathrm{y}}_{3}^{\prime}=\left(\mathrm{A}_{1}^{\prime}+\overline{\mathrm{T}}_{\mathrm{l}}\right)+\left(\mathrm{A}_{1}^{\prime}+2 \overline{\mathrm{~T}}_{1}\right)=120.95
\end{aligned}
\]

A factory uses exponential smoothing corrected for trend with \(\alpha=\beta=0.15\). The actual demand for the current month is
\(y_{t}=40\). Find the forecast for the next month and Month 6. Data for estimating \(A_{0}, \overline{T_{0}}\) :
The monthly demands in the previous year are as follows:
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|l|l|}
\hline month & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\
\hline demand & 4 & 6 & 8 & 10 & 14 & 18 & 20 & 22 & 24 & 28 & 31 & 34 \\
\hline
\end{tabular}

\section*{Solution}
\[
\mathrm{A}_{1}=\alpha \mathrm{y}_{1}+(1-\alpha) A_{0}
\]
\(A_{0}\) ( forecast for the current period with simple exponential smoothing) is taken the actual demand of the last month of the previous year plus \(\overline{T_{0}}: A_{0}=34+\overline{T_{0}}=36.73\)

The average of the trends of all eleven " 2 successive periods" in the last year:
\[
\frac{(34-3()+(3 x-22)+(26-24)+\ldots-\nmid)+(\not)-4)}{11}=\frac{34-4}{11}=2.73
\]

Note that for calculating \(\bar{T}_{0} \mathrm{~m}\) in practice the actual demand of the first and the last month was enough.
\[
\begin{aligned}
& A_{0}=34+2.73=36.73 \\
& A_{1}=0.15 \times 40+(1-0.15) \times 36.73=37.22 \\
& \overline{\mathrm{~T}}_{1}=0.15 \mathrm{~T}_{1}+(1-0.15) \overline{\mathrm{T}}_{0}=0.15\left(\mathrm{~A}_{1}-\mathrm{A}_{0}\right)+(1-0.15) \overline{\mathrm{T}}_{0} \\
& =0.15 \times(37.22-36.73)+(1-0.15) \times 2.73=2.39, \\
& \mathrm{~A}_{1}^{\prime}=\mathrm{A}_{1}+\frac{1-0.15}{0.15} \times \overline{\mathrm{T}}_{1}=37.22+5.67 \times 2.39=50.77, \\
& \hat{\mathrm{y}}_{2}^{\prime}=\mathrm{A}_{1}^{\prime}+1 \overline{\mathrm{~T}}_{1}=53.16, \quad \hat{\mathrm{y}}_{7}^{\prime}=\mathrm{A}_{1}^{\prime}+6 \overline{\mathrm{~T}}_{1}=65.11 . \boldsymbol{\Delta} \\
& \text { Example } 6-8
\end{aligned}
\]

The demand for a product during 24 periods are given in the second column of Table 6-7. Using double exponential smoothing calculate the forecast for Periods 1 through 24. \(\alpha=0.1, \beta=0.2 \bar{T}_{0}=\) initial Trend \(=0, A_{0}=\) the mean pf the actual values before period \(1=196.2\)

\section*{Solution}

The calculations are shown in Table 6-7. The calculations were done by the following MATLAB code.
```

alpha=input('Insert alpha e.g. 0.1 ') ');
beta=input('Insert beta e.g. 0.2 ');
A0=input('Insert A0 e.g. $196.2 \quad$ ');
Tbar0 $=$ input('Insert Tbar0 e.g. 0
$\mathrm{N}=$ input('Insert number of periods e.g. 24 ');

\section*{6-12 Forecasting techniques for time series having seasonal variations}

There might be 3 kind of variations in a time series:
Seasonal variations, cyclic variations and irregular (random) variations; the first 2 kinds are forecast-able and the last kind is systems' inherent property(Houshyar,...).

Consider a time series whose scatter plot is similar to Fig. 611. As the figure shows there are seasonal or cyclic variations in the series.

Fig. 6.11 A time series with seasonal variations
In such cases the use of the previous methods such as pure linear regression do not answer. Some methods have been developed to deal with these cases e.g. ratio- trend analysis and winter's method. The latter is described below.

\section*{6-12-1 Ratio-to-trend technique for seasonal adjustment}

The steps of a Ratio-to-trend method to forecast the future based on a time series that has shown trend and seasonal variations are as follows( based on Housyar, 1985 ):

Step 1: calculate the forecasts \(\left(\hat{y}_{t} ' s\right)\) for all periods of the time series by a common method such a regression or moving average.

Step 2: calculate the ratio of the observed value \(\left(y_{t}\right)\) to the predicted value \(\left(\hat{y}_{t}\right)\) for each period calculated in step 1:
\[
\begin{equation*}
R_{t}=\frac{y_{t}}{\hat{y}_{t}} \quad \mathrm{t}=1, \ldots, \mathrm{~m} \times \mathrm{n} \tag{6-27}
\end{equation*}
\]

Where
\(R_{t} \quad\) The ratio of actual value to the corresponding predicted value(for period \(t\) )
\(\mathrm{m} \quad\) No of cycles in a time horizon say in a year
n No of observed values in each cycle
Step 3:There are similar(= of the same name) seasons in the time series. For each of these seasons a separate \(R_{t}\) has been computed using Eq. 6-27. Calculate the mean of these \(R_{t}\) 's calculated for similar seasons :
\(\bar{R}_{j}=\frac{R_{j}+R_{j+N}+R_{j+2 N}+\ldots+R_{j+(m-1) N}}{m} \quad \mathrm{j}=1, \ldots, \mathrm{~N}\)
Where N is the number of periods in the iterative cycle e.g. 2 half-year in a year 4 seasons in a year.
call \(\bar{R}_{J}\) the index of Season j .
Step 4 The forecast with seasonal adjustment for period \(t\) is given by:

\section*{Example 6-9}
\[
\hat{y}_{t}^{\prime}=\bar{R}_{j} \times \hat{y}_{t} \quad(6-27-2)
\]

A manufacture' sale during the past 3 years has been is
\begin{tabular}{llllll}
3.5000 & 4.0000 & 6.0000 & 8.0000 & 4.0000 & 5.0000 \\
7.0000 & 9.0000 & 4.5000 & 7.5000 & 9.0000 & 3.5000
\end{tabular}

Apply ratio-to-trend method to forecast the sale.

\section*{Solution}

As the following scatter plot shows there is seasonal variation in the sale data. Therefore the above method might be appropriate.

Step 1 If we use simple regression with period(t) as the dependent variable to fore cast the sale volume we would obtain:
\(\hat{y}_{t}=4.6667+0.1923 t\). Column 5 of Table \(6-8\) shows the primary forecasts \(\left(\hat{y}_{t}\right)\) for all the 12 periods using this relationship
Step 2 Column 6 shows the ratio of the observed value \(\left(y_{t}\right)\) to the predicted value \(\left(\hat{y}_{t}\right)\) for each period. The scatter plot shows every 4 periods, we have an iterative cycle ; therefore \(N=4\) and 4 seasonal indices have to be calculated in order to correct \(y_{t}\) for seasonal adjustment:
\(\overline{\mathrm{R}}_{1}=\frac{0.7203+0.7107+0.7034}{3}=0.7115, \overline{\mathrm{R}}_{2}=0.9297\), \(\overline{\mathrm{R}}_{3}=1.2118, \quad \overline{\mathrm{R}}_{4}=1.1413\)
Step 3 The corrected forecast \(\left(\hat{y}_{i}^{\prime}\right)\) for period \(i\) is obtained from \(\hat{y}_{i}\) in Column 5 multiplied by the corresponding seasonal index ( \(\overline{R_{1}}, \overline{R_{2}}, \overline{R_{3}}, \overline{R_{4}}\) ). The result is given in Column 7. The RMSE between the \(\hat{y}_{i}^{\prime}\) and \(y_{i}\) is \(\mathrm{rmse}=\operatorname{sqrt}\left(\operatorname{mse}\left(y-y^{\prime}\right)\right)=1.6\)

Using MATLAB command corrcoef \(\left(\mathrm{y}, \mathrm{y}^{\prime}\right)\) gives the correlation coefficient between the \(\hat{y}_{i}^{\prime}\) and \(y_{i}\) is 0.62 .1
The forecast for Period 13 is calculated as follows:
\(\hat{y}_{13}=(4.6667+0.1923 \times 13) \times 0.7115 \cong 5.1\).
Table 6-8 A time series data and its forecast by Ratio-to- trend method
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline Year & Season & t & \(y_{t}\) & \begin{tabular}{l}
\(\hat{y}_{t}\) With \\
Regression
\end{tabular} & \(R_{t}\) & \[
\begin{aligned}
& \hat{y}_{t}^{\prime} \\
& \left(\hat{y}_{t} \times \bar{R}\right)
\end{aligned}
\] \\
\hline \multirow{4}{*}{one} & Spring & 1 & 3.5 & 4.8590 & 0.7203 & 3.46 \\
\hline & Summer & 2 & 4.0 & 5.0513 & 0.7919 & 4.70 \\
\hline & Fall & 3 & 6.0 & 5.2436 & 1.1443 & 6.35 \\
\hline & Winter & 4 & 8.0 & 5.4359 & 1.4717 & 6.20 \\
\hline \multirow[t]{4}{*}{Two} & Spring & 5 & 4.0 & 5.6282 & 0.7107 & 4.00 \\
\hline & Summer & 6 & 5.0 & 5.8205 & 0.8590 & 5.82 \\
\hline & Fall & 7 & 7.0 & 6.0128 & 1.1642 & 7.29 \\
\hline & Winter & 8 & 9.0 & 6.2051 & 1.4504 & 7.08 \\
\hline \multirow[t]{4}{*}{Three} & Spring & 9 & 4.5 & 6.3974 & 0.7034 & 4.55 \\
\hline & Summer & 10 & 7.5 & 6.5897 & 1.1381 & 6.13 \\
\hline & Fall & 11 & 9.0 & 6.7820 & 1.3270 & 8.22 \\
\hline & Winter & 12 & 3.5 & 6.9743 & 0.5018 & 7.96 \\
\hline
\end{tabular}

The time series data in this problem contain both trend ad seasonal variation. A method titled Winter's method might result in better forecasts for these kind of problems

It worth mentioning that artificial intelligence techniques such as artificial neural networks(ANNs) might be appropriate for forecasting problems.

Some artificial neural networks(ANNs) that are based on simple mathematical models of the brain could be used as forecasting methods. They allow complex nonlinear relationships between the response variable and its predictors (Hyndman \&Athanasopoulos,2018,p333).The last exercise of this chapter is on ANNs.

\section*{6-13 Verifying and controlling forecasters using control charts}

\author{
By: Massoud Hajghani, Hamid Bazargan,
}

A necessary first step after we have made a forecast is to verify that it does indeed appear to represent the data and the chance system underlying the demand for the product in question. To do a good job of forecasting requires that we continually compare the forecast against the actual demand and take action to revise the forecast when there is a statistically significant change in demand((Biegel, 1971, p51).

In this section we would like to determine the validity of the forecast values and the forecaster by appropriate statistical tools. To do this
1. we could use statistical tests,
2. we could calculate RMSE between the actual and observed values; the less this value the better the forecasting method
3. One could plot the observed values and the corresponding forecasts in an \(\mathrm{X}-\mathrm{Y}\) coordinate and fit a least-square-error line to them; the more the points closer to this line and this line closer to the bisector of the first quarter, the better the forecast values(See the last example of this chapter),

\section*{6-13-1 A control chart for forecast error}

As said before good job of forecasting requires continual comparison of the forecasts against the actual values. If there is evidence of satisfactory forecaster, the forecaster is trusted unless the evidence no longer exist. When this happens an appropriate forecasting technique has to replace the existing one. Control chart is a graph used to study how a process changes
over time; therefore an appropriate tool for continual monitoring is plotting control chart for forecast error. Biegel(1971) introduces a control chart to monitor the forecast. Since the concept of moving range from statistics and quality control is used in this chart, the concept is reminded below:

\section*{Definition of Moving Range(MR)}

Moving range denoted by MR, is dined here as follows:
\[
\begin{equation*}
M R=\left|\left(d_{t}^{\prime}-d_{t}\right)-\left(d_{t-1}^{\prime}-d_{t-1}\right)\right| \tag{6-28}
\end{equation*}
\]
where
\(d_{t}^{\prime} \quad\) The predicted value for Period t
\(d_{t} \quad\) The actual value of Period t
\(d_{t-1}^{\prime} \quad\) The predicted value for Period t
\(d_{t-1}\) The actual value of Period t .
An application of moving range here is to estimate the standard deviation of forecast error frm the following formula:
\[
\begin{equation*}
\widehat{\sigma}=\frac{\overline{M R}}{d_{2}} \tag{6-29}
\end{equation*}
\]
where
\(\overline{\mathrm{MR}}\) The predicted value for Period t defined as:
\[
\begin{equation*}
\overline{M R}=\sum \frac{M R}{k-1} \tag{6-30}
\end{equation*}
\]

Note that for k period k -1
\(d_{2} \quad\) is a coefficient obtainable from statistical quality control textbooks such as Bazargan(2020). Since the moving range here is defined as the difference of consecutive errors \((\mathrm{n}=2)\), the value of \(d_{2}\) is obtained equal to 1.128 from the books of the following MATLAB commands
\(\mathrm{n}=\cdots\);pd = makedist('normal', ,0,1);fun = @(x) (1-(1-
\(\operatorname{cdf}(\mathrm{pd}, \mathrm{x})) . \wedge \mathrm{n}-(\mathrm{cdf}(\mathrm{pd}, \mathrm{x})) . \wedge \mathrm{n}) ; \mathrm{d} 2=\) integral(fun,-inf,inf);

\section*{6-13-1-1 Upper and lower limits of the control chart for forecast error}

The control chart used in quality control usually have a central line (CL) and 2 limits: upper control limit(UCL)and lower control limit (LCL).

Since forecast error(e) is sometimes negative and sometimes positive, the central line of this chart is set to zero( \(\mathrm{CL}=\mathrm{E}(\mathrm{e})=0)\). The limits are determined from the MR values calculated according to Eq.(6-28). It is advised to have at least 10 and preferably 20 MR values in determining the control limits(Biegel,1971 p52). The upper control limit(UCL) and the lower control limit(LCL) of the control chart for forecast error are calculated from:
\[
\mathrm{UCL}=\mathrm{E}(\mathrm{e})+3 \sigma_{\mathrm{e}}=0+3 \frac{\overline{\mathrm{MR}}}{\mathrm{~d}_{2}}=3 \frac{\overline{\mathrm{MR}}}{1.128}=2.66 \overline{\mathrm{MR}}
\]

CL=0
LCL \(=E(\mathrm{e})-3 \sigma_{\mathrm{e}}=0-3 \frac{\overline{\mathrm{MR}}}{\mathrm{d}_{2}}=-2.66 \overline{\mathrm{MR}}\)
Assuming the error is normally distributed, it is expected to have \(0.27 \%\) of the points plotted on the chart to fall out of the above 3 -sigma limits. In other words if we plot 10000 points on the chart, 27 points are expected to fall outside the limits; from 1000 points 3 points. Since our data are not that much if the forecasts are good no point is allowed to fall outside the limits. Therefore if a point is out of control due to falling outside the limits or is out of control due to the criteria or tests described later, when verifying the forecaster we have to do one of the followings(Biegel, 1971 p52):

Discard some data(those points from a different cause system) ;search for a new forecaster

Needles to say that if a point is outside the limits, we have to investigate the cause and try to resolve the problem.

If all points fall randomly inside the limits and form no special pattern, we could rely with certainty upon the existing forecasting method.

If points fall outside the limits we apparently do not have the correct forecasting equations and they should be revised accordingly. We can use the control chart to tell us where the change occurred and ca determine a forecasting equation from the data appropriate to the present cause system (Biegel,1971 p53)

\section*{6-13-1-2 Some criteria for out-of- control status}

As wells as the case mentioned above to declare an out of control status, there are some criteria or tests based on runs of points above or below the central line of the chart

To mention the criteria, the control chart is divided into 3 regions \(\mathrm{A}, \mathrm{B}\) and C above and below the central line as shown in Fig. 6-12.

Fig. 6.12 Regions A, B and C in chart for forecast error (based on Biegel, 1971)
Region A is within \(\pm 2 \sigma_{\mathrm{e}}= \pm 2 \frac{\overline{\mathrm{MR}}}{\mathrm{d}_{2}=1.128}= \pm 1.77 \overline{\mathrm{MR}}\) above and below the central line.

Region B is within \(\pm 1 \sigma_{\mathrm{e}}= \pm \frac{\overline{\mathrm{MR}}}{\mathrm{d}_{2}=1.128}= \pm 0.86 \overline{\mathrm{MR}}\) above and below the central line.
Region C is the region above and below the central line.
Two tests that check out-of-control status in a control chart for error are (Biegel,1971p54):
1. Of 3 successive points, at least 2 points fall on the same side of the central line in Region A
2. Of 5 successive points, at least 4 points fall on the same side of the central line in Region B.
Grant \& Levenworth(1988) suggest the following tests to detect shifts in a universe parameter(here: forecast error) in of applications control chart in manufacturing:
There is suspicion that the process parameter has changed if (grant \&Leavenworth ,1988 page 89):
- Whenever in 7 successive points on the control chart, all are on the same side of the central line(a run of 7 points all above or all below the central line).
- In 11 successive points on the control chart, at least 10 are on the same side of the central line.
- In 14 successive points on the control chart, at least 12 are on the same side of the central line.
- In 17 successive points on the control chart, at least 14 are on the same side of the central line.
- In 20 successive points on the control chart, at least 16 are on the same side of the central line.

The sequences mentioned in each of these rules will occur as a matter of chance, with no change in the universe(here: error), more frequently than will a point outside of 3 -sigma limits. For this reason they provide a less reliable basis for hunting a trouble than does the occurrence of a point outside of control limits(Grant\& Leavenworth, 1988 page89). Those interested in the theoretical basis for the rules may refer to Chapter 6 of Grant and Leavenworth(1988).

\section*{6-13-2 Illustrations}

Below are some illustrations showing how the control chart is used for forecasts verification. In the cases where some conditions of out-of-control appear, necessary actions have to be taken e.g. to modify the current forecast equations by removing the data points that apparently are not from the same cause system(Biegel, 1971,page55). The following symbles are used in the examples:
\(t\) period
d demand
d' Forecast
e error
MR Moving Range
CL Central Line
UCL Upper Control Limit
LCL Lower Control Limit

\section*{Example 6-10 verifying constant forecasters}
\(d^{\prime}=\frac{\sum d_{t}}{12}=\frac{1191}{12} \cong 99\) is used to forecast the demand a time series of which is given in the following table
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|l|l|}
\hline period & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\
\hline demand & 90 & 111 & 99 & 89 & 87 & 84 & 104 & 102 & 95 & 114 & 103 & 113 \\
\hline
\end{tabular}

Use a control chart to verify the constant forecaster.

\section*{Solution}
\[
\begin{aligned}
& \mathrm{UCL}_{\mathrm{e}}=2.66 \overline{\mathrm{MR}}, \quad \mathrm{CL}=0, \quad \mathrm{LCL}_{\mathrm{e}}=-2.66 \overline{\mathrm{MR}} \\
& \overline{\mathrm{MR}}=\frac{117}{11}=10.6, \mathrm{UCL}=28.2 \quad \mathrm{LCL}=-28.2
\end{aligned}
\]

The calculations have been done in the following table and MR points have been plotted in Fig. 10-13.
\begin{tabular}{|c|c|c|c|c|}
\hline period & \(\mathrm{d}_{\mathrm{t}}\) & \begin{tabular}{l} 
Forecast \\
\(\left(d^{\prime}\right)\)
\end{tabular} & \begin{tabular}{l}
\(e=\) \\
\(d^{\prime}-d\)
\end{tabular} & \begin{tabular}{l}
\(M R=\) \\
\(\mid\left(d_{t}^{\prime}-d_{t}\right)-\left(d_{t-1}^{\prime}-d_{t-1}\right)\)
\end{tabular} \\
\hline 1 & 90 & 99 & 9 & \\
\hline 2 & 111 & 99 & -12 & 21 \\
\hline 3 & 99 & 99 & 0 & 12 \\
\hline 4 & 89 & 99 & 10 & 10 \\
\hline 5 & 87 & 99 & 12 & 2 \\
\hline 6 & 84 & 99 & 15 & 3 \\
\hline 7 & 104 & 99 & -5 & 20 \\
\hline 8 & 102 & 99 & -3 & 2 \\
\hline 9 & 95 & 99 & 4 & 7 \\
\hline 10 & 114 & 99 & -15 & 19 \\
\hline 11 & 103 & 99 & -4 & 11 \\
\hline 12 & 113 & 99 & -14 & 10 \\
\hline sum & 1191 & 1188 & -3 & 117 \\
\hline
\end{tabular}

The chart indicates a stable cause(Biegel, 1971, page 55) because no point is out of the control limits and none of the tests applies.

Fig. 6.13 Control chart showing forecast error of Example 6-10 (Biegel, 1971, p55)

\section*{Example 6-11 Verifying linear forecasters}

The actual demand for the 12 periods of the last year have been given in the following table. Forecasting was done by
simple linear regression. The resulted function for forecasting was \(193+3 t\) given by the following commands in MATLAB environment:
\[
\begin{aligned}
& \mathrm{y}=\left[\begin{array}{llllllllll}
199 & 202 & 199 & 208 & 212 & 194 & 214 & 220 & 219 & 234
\end{array}\right. \\
& 219 \text { 233]';t=[1:12]'; T=[ones(size(t)) t];ab=regress(y,T) }
\end{aligned}
\]

Calculate the moving ranges for errors, plot the control chart and comment.

\section*{Solution}

The calculations have been done in the following table and MR points have been plotted in Fig. 6-14.
\begin{tabular}{|c|c|c|c|c|}
\hline t & d & \(d^{\prime}\) & \(d^{\prime}-d\) & \((\mathrm{MR})\) \\
\hline 1 & 199 & 196 & -3 & \\
\hline 2 & 202 & 199 & -3 & 0 \\
\hline 3 & 199 & 202 & 3 & 6 \\
\hline 4 & 208 & 205 & -3 & 6 \\
\hline 5 & 212 & 208 & -4 & 1 \\
\hline 6 & 194 & 211 & 17 & 21 \\
\hline 7 & 214 & 214 & 0 & 17 \\
\hline 8 & 220 & 217 & -3 & 3 \\
\hline 9 & 219 & 220 & 1 & 4 \\
\hline 10 & 234 & 223 & -11 & 12 \\
\hline 11 & 219 & 226 & 7 & 18 \\
\hline 12 & 233 & 229 & -4 & 11 \\
\hline sum & 2553 & & -3 & 99 \\
\hline
\end{tabular}
\[
\begin{aligned}
& \mathrm{UCL}_{\mathrm{e}}=2.66 \overline{\mathrm{MR}}, \mathrm{CL}=0, \mathrm{LCL}_{\mathrm{e}}=-2.66 \overline{\mathrm{MR}} \\
& \overline{\mathrm{MR}}=\frac{99}{11}=9.0 \quad \text { UCL }=23.9 \quad \text { LCL }=-23.9
\end{aligned}
\]

Fig 6-14 The control chart foe Example 6-11
(based on Biegel, 1971)
The chart in Fig.6-14 shows a stable cause system and a statistically valid forecasting function(Biegel, 1971, page 57) because points are distributed randomly within the limits, no point falls out of the limits and none of the tests applies.

\section*{Example 6-12 Verifying a cyclic forecaster}

Consider the forecasting function
\[
\mathrm{d}_{\mathrm{t}}^{\prime}=495.6+5.7 \mathrm{t}-10.8 \cos \frac{\pi}{6} t+4.9 \sin \frac{\pi}{6} t
\]
proposed \({ }^{1}\) to forecast the demand given in the following table.
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|l|l|}
\hline period & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\
\hline demand & 72 & 83 & 92 & 107 & 114 & 129 & 91 & 108 & 116 & 79 & 92 & 93 \\
\hline
\end{tabular}

Calculate the moving ranges for errors, plot the control chart and comment.

\section*{Solution}

The calculations have been done in the following table and MR points have been plotted in Fig. 6-15.

\footnotetext{
\({ }^{1}\) To see how it has been derived one might refer to Biegel(1971) page 34.
}
\(\mathrm{UCL}=2.66 \overline{\mathrm{MR}}, \quad \mathrm{CL}=0, \quad \mathrm{LCL}=-2.66 \overline{\mathrm{MR}}\)

\begin{tabular}{|c|c|c|c|c|}
\hline\(t\) & \(d\) & \(d^{\prime}\) & \(d^{\prime}-d\) & MR \\
\hline 1 & 72 & 82 & 10 & \\
\hline 2 & 83 & 87 & 4 & 6 \\
\hline 3 & 92 & 95 & 3 & 1 \\
\hline 4 & 107 & 103 & -4 & 7 \\
\hline 5 & 114 & 110 & -4 & 0 \\
\hline 6 & 129 & 114 & -15 & 11 \\
\hline 7 & 91 & 114 & 23 & 38 \\
\hline 8 & 108 & 109 & 1 & 22 \\
\hline 9 & 116 & 101 & -15 & 16 \\
\hline 10 & 79 & 93 & 14 & 29 \\
\hline 11 & 92 & 86 & -6 & 20 \\
\hline 12 & 93 & 82 & -11 & 5 \\
\hline & 1176 & & 0 & 155 \\
\hline
\end{tabular}

Fig. 6-15 The control chart for Example 6-12(based on Biegel, 1971)
The control chart in Fig 6.15 shows a status of in-control. Therefore it is concluded that we have a statistically valid forecasting function.

\section*{Example 6-13 Verifying a linear-cyclic forecaster}

Consider the forecasting function
\[
\mathrm{d}_{\mathrm{t}}^{\prime}=495.6+5.7 \mathrm{t}-10.8 \cos \frac{\pi}{6} t+4.9 \sin \frac{\pi}{6} t \quad \text { proposed }^{1} \text { to }
\]
forecast the demand given in the following table.
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|l|l|}
\hline t & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\
\hline d & 498 & 505 & 517 & 521 & 535 & 548 & 544 & 546 & 529 & 548 & 543 & 557 \\
\hline
\end{tabular}
plot the control chart and comment.

\section*{Solution}

The calculations have been done in the following table and MR points have been plotted in Fig. 6-15.
\[
\overline{\mathrm{MR}}=\frac{82}{11}=7.4 \quad \mathrm{UCL}=19.7 \quad \mathrm{LCL}=-19.7
\]
\begin{tabular}{|c|c|c|c|c|}
\hline\((\mathrm{t})\) & \(\left(d^{\prime}\right)\) & \((\mathrm{d})\) & \(d^{\prime}-d\) & \((\mathrm{MR})\) \\
\hline 1 & 494 & 498 & -4 & \\
\hline 2 & 506 & 505 & 1 & 5 \\
\hline 3 & 518 & 517 & 1 & 0 \\
\hline 4 & 528 & 521 & 7 & 6 \\
\hline 5 & 536 & 535 & 1 & 6 \\
\hline 6 & 541 & 548 & -7 & 8 \\
\hline 7 & 542 & 544 & -2 & 5 \\
\hline 8 & 542 & 546 & -4 & 2 \\
\hline 9 & 542 & 529 & 13 & 17 \\
\hline 10 & 543 & 548 & -5 & 18 \\
\hline 11 & 546 & 543 & 3 & 8 \\
\hline 12 & 553 & 557 & -4 & 7 \\
\hline & & 6391 & 0 & 82 \\
\hline
\end{tabular}

\footnotetext{
\({ }^{1}\) To see how it has been derived one might refer to Biegel(1971) pp 36-39.
}

Fig. 6.16 Error control chart for Example 6-13 ( Biegel, 1971p 59)
As with 3 above examples, no point is out of the the control chart in Fig 6.16 m , no special pattern has been formed and none of the tests apply. Therefore we have a state of in-control and could rely upon the forecasting function as far as no evidence of being out-of-control appears.

\section*{Example 6-14}

Perhaps the real test of the control chart con on this example(based on Bigel, 1971 page 41 and 60 ), since the data was from real world. The following table shows monthly "Revenrue Miles flown" on an international carrier.
\begin{tabular}{|l|c|c|c|c|c|c|}
\hline\(t\) & 1 & 2 & 3 & 4 & 5 & 6 \\
\hline \begin{tabular}{l} 
Miles \\
flown(d)
\end{tabular} & 10885 & 10465 & 10143 & 9273 & 9378 & 9378 \\
\hline \multicolumn{1}{|c|}{t} & 7 & 8 & 9 & 10 & 11 & 12 \\
\hline \begin{tabular}{l} 
Miles \\
flown(d)
\end{tabular} & 8705 & 10091 & 10145 & 10995 & 11605 & 12311 \\
\hline
\end{tabular}

The following linear cyclic function was suggested to forecast d (for details of the computations see Biegel,1971p41):
\[
d_{t}^{\prime}=9450+133 t+1110 \cos \frac{\pi}{6} t+329 \sin \frac{\pi}{6} t
\]

Is this a reliable forecasting function for the Miles flown(d)?

\section*{Solution}

To verify the function, the moving ranges are calculated and the error control chart is plotted.
\[
\overline{\mathrm{MR}}=\frac{4600}{11}=418.2 \quad \mathrm{UCL}=2.66 \overline{\mathrm{MR}}=1112 \quad \mathrm{LCL}=-2.66 \overline{\mathrm{MR}}=-1112
\]

The following table shows the computations results
\begin{tabular}{|c|c|c|c|c|}
\hline\(t\) & \(d\) & \(d^{\prime}\) & \(d^{\prime}-d\) & MR \\
\hline 1 & 10885 & 10709 & -176 & \\
\hline 2 & 10465 & 10556 & 91 & 267 \\
\hline 3 & 10143 & 10178 & 35 & 56 \\
\hline 4 & 9273 & 9712 & 439 & 404 \\
\hline 5 & 9768 & 9318 & 450 & 889 \\
\hline 6 & 9378 & 9137 & -241 & 209 \\
\hline 7 & 8705 & 9254 & 549 & 790 \\
\hline 8 & 10091 & 9672 & -419 & 968 \\
\hline 9 & 10145 & 10316 & 171 & 590 \\
\hline 10 & 10995 & 11049 & 53 & 118 \\
\hline 11 & 11605 & 11708 & 103 & 50 \\
\hline 12 & 12311 & 12154 & -156 & 259 \\
\hline sum & 123764 & 123763 & -1 & 4600 \\
\hline
\end{tabular}

For example for Period 8 :
\[
\begin{aligned}
& \mathrm{t}=8 ; \mathrm{d}^{\prime}=9450+133 * \mathrm{t}+1110 * \cos \left(\mathrm{pi}^{*} \mathrm{t} / 6\right)+329 * \sin \left(\mathrm{pi}^{*} \mathrm{t} / 6\right) \\
& \text { ans }=9674 . \\
& \mathrm{t}=7 ; \mathrm{d}^{\prime}=9450+133^{*} \mathrm{t}+1110^{*} \cos \left(\mathrm{pi}^{*}+/ 6\right)+329 * \sin \left(\mathrm{pi}^{*} \mathrm{t} / 6\right) \\
& \text { ans }=9255 .
\end{aligned}
\]
\[
t=8, M R_{8}=\left|\left(d_{8}^{\prime}-d_{8}\right)-\left(d_{8-1}^{\prime}-d_{8-1}\right)\right|=|9674-10093-(9255-8705)|=969
\]

These results some how differs from those in the table; the reason could be due to rounding up the numbers.

Fig 6-17 The error control chart for Example 6-14 (based on Biegel, 1971, p60)

Figure 4.6 shows the error control chart which indicates an in-control status and then a valid estimator function(Biegel,1971 p60).

The reader should bear in mind that the discussion of occurrences and actions tends to eliminate the time aspect which is present in the generation of data. For the remainder of of this chapter he should assume that the demand data become available to us , piece by piece, over a span of time.

\section*{Example 6-15}

In Example 6.10 We have forecast the demand should average 99 . Suppose the demand for the 7 month of the second year is:
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline month & 13 & 14 & 15 & 16 & 17 & 18 & 19 \\
\hline d & 105 & 89 & 114 & 109 & 112 & 107 & 116 \\
\hline\(d^{\prime}-d *\) & -6 & 10 & -15 & -10 & -13 & -8 & -17 \\
\hline\(* d^{\prime}=99\)
\end{tabular}

Plot a new error control chart related to Moth 1 through 19. Comment and do the necessary actions.

\section*{Solution}

Figure 6.18 shows the control chart for the new data and the data related to the year before. In this chart the point related to period 19, marked with \(X\), indicates an out-of control condition(4 out of 5 successive points in Region B). This means that the forecaster is underestimating the demand(Biegle,1971 p 61).

Fig 6.18 Error control chart for 19- period time horizon related Example 6-10 (based on Biegel, 1971 p62)

The out- of -control condition indicates a necessity to establish a new forecaster. As a first attempt the mean of all the data was examined to see if it fits. The result of the calculations are (Biegel,1971 page 63)
\[
\bar{d}=\frac{1943}{19}=102 \quad \overline{M R}=10.4 \quad U C L=27.8 \quad L C L=-27.8
\]

Standard deviation of 19 demand values is \(S_{d}=10.44\)
A new constant forecaster is chosen \(: d^{\prime}=102\). Suppose the demands for the rest of the second year is as follows
\begin{tabular}{|l|l|l|l|l|l|}
\hline period & 20 & 21 & 22 & 23 & 24 \\
\hline demand(d) & 105 & 109 & 93 & 110 & 116 \\
\hline
\end{tabular}

Fig 19.6 shows the chart for the first and the second year .

Fig. 6-19 Final control cart for 24-period data of Examples 6-10 and 6-15 (based on Biegel, 1971)

It is found the chart shows statistical control. There fore \(\mathrm{d}^{\prime}=102\) is a better forecaster than \(\mathrm{d}^{\prime}=99\). This same cart should be used until we have evidence of lack of control(Biegle, 1971 p62)

\section*{Example 6-16}

In Example 6-11, suppose the actual demand values for the 7 month of Year 2 (i.e Periods 13 through19) were 209, 226,224, 221, 250, 235, 233.
a)Use the same forecaster and error chart used in Example 11-6 to show the forecast error for Period 13 to 16 and comment.
b) If there is an indication of out-of-control status, What is your suggestion?

\section*{Solution}
a)

Using \(d_{t}^{\prime}=193+3 t\) to forecast the demand for periods 13 through 15 and calculate error \(=\mathrm{d}\) '-d yields:

If we plot the errors of Periods \(13-16\) on the chart of Example 6-11 we would obtain the following chart. Of 5 successive points \(12,13,14, .15,16\), four points fall above the central line in Region B, which indicates a state of out of control.

Fig 6-20 Control chart for first 16 month of Example 6-11
(Bielgel 1971 page 64)
b)

A new for regression forecaster based on the 16-month demand data is calculated using the following MATLAB commands:
\begin{tabular}{|c|c|c|}
\hline \(\mathrm{y}=\left[\begin{array}{ll}199 & 202\end{array}\right.\) & 199208 & \(\begin{array}{llllll}212 & 194 & 214 & 220 & 219 & 234\end{array}\) \\
\hline 219233209 & 226224 & 221]';t=[1:16]'; T=[ones(size(t)) \\
\hline t];ab=regress \((\mathrm{y}, \mathrm{T})\) & & \\
\hline
\end{tabular}

Although the answer is \(\mathrm{a}=198.9000\) and \(\mathrm{b}=1.8426\), but the forecaster is chosen as: \(d^{\prime}=199+2 t\).

The new limits ( based on 16 periods) are:
\[
\overline{M R}=\frac{99+27+14+5+6}{15} \cong 10.1 \quad U C L=26.9 \quad L C L=-26.9
\]

The new chart for 16 periods is shown in Fig 6.21. Since it shows a sate of in control, it it is concluded that the new forecasting function is satisfactory(Biegel,1971, page63).

Fig 6-21 control chart for !6-period data of Examples 6-11 \& 6-15 (based on Biegel, 1971)

Although the data for the rest of Year 2 is not given in this example, the control chart for both years has been redrawn in Fig. 6.22 from Fig. 4.8 on page 63 Biegel(1971).

Fig 6-22 New chart for 24 periods of Examples 6-11 \&6-16
(Biegel, 1971 p65)
This control chart should be used until a sign of out of control appears.

\section*{Example 6-17}

Plot the actual and predicted values related to 19 periods of Example 6-16 in an X-Y coordinates and calculate RMSE. How do you evaluate the forecasting function \(d^{\prime}=199+2 t\) ?
Solution
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|}
\hline month & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\
\hline demand(y) & 199 & 202 & 199 & 208 & 212 & 194 & 214 & 220 & 219 & 234 \\
\hline Forecast ( \(\widehat{\mathrm{y}}\) ) & 196 & 199 & 202 & 205 & 208 & 211 & 214 & 217 & 220 & 223 \\
\hline month & 11 & 12 & 13 & 14 & 15 & 16 & 17 & 18 & 19 & \\
\hline demand(y) & 219 & 233 & 209 & 226 & 224 & 221 & 233 & 235 & 250 & \\
\hline Forecast \((\hat{\mathrm{y}})\) & 226 & 230 & 238 & 241 & 244 & 247 & 250 & 253 & 256 & \\
\hline
\end{tabular}

The above table shows the values and the following MATLAB commands has plotted Fig. 6.23
>> yhat=[196 199 202205208211214217220223226230238
241244247250253 256]';y=[199 202199208212194214220219
234219233209226224221233235 250]';
\(\mathrm{Y}=[\) ones(size(y)) y];ab=regress(yhat,Y);plot(y,yhat,'+');
\(\mathrm{xp}=190: 0.01: 250 ; \mathrm{yp}=\mathrm{ab}(1)+\mathrm{ab}(2) * \mathrm{xp} ;\) hold on;plot(xp,yp)

Fig 6-23 Actual demand(y) and forecast (yhat) for 19 months of Example 6-16

RMSE \(=\) sqrt(mse( y -yhat)) in MATLAB gives RMSE \(=13.2208\).

From Fig 5-23 it is evident that the points are around the line and the line is near to the bisector of the first quarter. Then the forecasts could be acceptable.

\section*{Exercises}

1-Thefollowing table shows the maintenance cost per annum for a kind of vehicle versus the age of the vehicle and annual vehicle mileage.
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|}
\hline \begin{tabular}{l} 
Maintenance \\
Cost
\end{tabular} & 832 & 733 & 647 & 553 & 467 & 373 & 283 & 189 & 96 \\
\hline \begin{tabular}{l} 
Annual \\
Mileage \((\times 1000)\)
\end{tabular} & 6 & 7 & 9 & 11 & 13 & 15 & 17 & 18 & 19 \\
\hline \begin{tabular}{l} 
Age at the \\
beginning of the \\
current year
\end{tabular} & 8 & 7 & 6 & 5 & 4 & 3 & 2 & 1 & 0 \\
\hline
\end{tabular}
a)Find the correlation coefficient between the cost and the mileage and between the cost and the age.
b) Find the simple regression forecaster for the better correlation coefficient obtained in a.
c) Use a software such as MATLAB, Minitab, Lotus to forecast the cost form a 2 -variabe(age and mileage) regression equation.
d) What would be the cost forecast from the forecasters in \(b\) and c if the age and the mileage are 3.5 years an 16000 respectively.
2. Find the regression equation for predicting cost from age in Problem 1. Forecast all the costs from the given corresponding age in the table. How much is RMSE between the actual costs and the predicted costs? How much is the correlation coefficient between the age and the predicted costs. Use the \(t\)-test for paired data to compare the mean of the actual costs and the predicted \(\operatorname{costs}(\alpha=10 \%)\).
3. Suppose in the past 10 years, the increase in the price of iron compared to the price in Year 0 is as given in the following table. Also suppose the increase in the price of a specific commodity for the same time horizon is also given in the table. Could it be concluded that the increase in the price of the commodity compared to Year 0 is proportional to the price increase of iron?

Is it better to forecast the increase in the commodity price from the increase in the price of iron or from year no. ?
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|}
\hline Year No. & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\
\hline \begin{tabular}{l} 
Increase \\
In Iron \\
price
\end{tabular} & 100 & 102 & 103 & 110 & 121 & 124 & 127 & 130 & 139 & 145 \\
\hline \begin{tabular}{l} 
Increase \\
In the \\
commodity \\
price
\end{tabular} & 100 & 103 & 106 & 119 & 126 & 127 & 128 & 123 & 140 & 144 \\
\hline
\end{tabular}
4.A vendor believes that the demand for one of his goods depend on the number of houses built exactly 3 month ago in a district. Use the following table to verify his claim. Find the regression relationship to forecast the sale of the vendor from the number houses. Is it better to forecast the increase in the slae from the number houses built exactly 3 month ago o from month no. ?
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|l|l|}
\hline \begin{tabular}{l} 
Month \\
no
\end{tabular} & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\
\hline \begin{tabular}{l} 
Sale \\
volume \\
(x \\
1000)
\end{tabular} & 45 & 60 & 62 & 30 & 40 & 45 & 68 & 75 & 80 & 45 & 30 & 25 \\
\begin{tabular}{l} 
Housses \\
built \((\times\) \\
\(10)\)
\end{tabular} & 26 & 25 & 32 & 38 & 50 & 48 & 32 & 40 & 35 & 25 & 10 & 15 \\
\hline
\end{tabular}
5.Using the time series given in the following table, determine which N has the least RMSE for using in N -period simple moving average (with equal weighting)?
\begin{tabular}{|l|l|l|l|l|l|l|}
\hline t (month) & 1 & 2 & 3 & 4 & 5 & 6 \\
\hline sale & 30 & 32 & 30 & 39 & 32 & 34 \\
\hline
\end{tabular}
6.In Problem 5 if we want to replace moving average with simple exponential smoothing, calculate the appropriate \(\alpha\). Forecast the sale volume for Month 7 if
a) the sale forecast for Month 1 is 32
b)we want to use the mean of the data as the forecast required in the exponential smoothing formula.
7. Use the following data and 2-period weighted moving average to forecast the quantity for Periods 3 through 10 . Use a weight of 0.55 for just the previous month and a weight of 0.45 for the other month.
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|}
\hline Month & Ja & F & M & Ap & M & J & Ju & Au & S \\
\hline Quantity & 19.36 & 25.45 & 19.13 & 21.48 & 20.77 & 25.42 & 23.79 & 28.35 & 26.80 \\
\hline
\end{tabular}
8. Choose ratio-to-trend algorithm to forecast the quantity for all periods of the previous problem. Calculate The RMSE and the correlation coefficient between the actual and the predicted quantities. Apply the paired data \(t\)-test. Compare this algorithm with the one used in Problem 7.
9. The following table shows the sale volume of a store of home appliances during the past 10 half-years. Predict the sale for Year 7.
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|}
\hline \begin{tabular}{l} 
Half- \\
year
\end{tabular} & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\
\hline sale & 15.5 & 14.2 & 15.1 & 12.9 & 14.8 & 12.5 & 14.4 & 13.2 & 16.50 & 15 \\
\hline
\end{tabular}
10. The demand for a product in January was 65 and during the previous year were as given in the table below. Forecast the demand for February using the regression method and double exponential smoothing with \(\alpha=\beta=0.1\).
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|l|l|}
\hline t (month) & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\
\hline demand & 52 & 48 & 36 & 49 & 65 & 54 & 60 & 48 & 51 & 62 & 66 & 62 \\
\hline
\end{tabular}
11. The following data shows various thickness of a plastic reservoir and the corresponding air pressure blown when it was being produced. Is there a linear correlation between the air pressure and the thickness?
\begin{tabular}{|l|l|l|l|l|l|}
\hline \begin{tabular}{l} 
Air pressure \\
\(\left(\mathrm{kgf} / \mathrm{cm}^{2}\right)\)
\end{tabular} & 10.0 & 9.5 & 9.0 & 8.5 & 8.0 \\
\hline \multirow{4}{*}{ Wall thickness(mm) } & 1.83 & 2.86 & 3.21 & 4.12 & 4.62 \\
\cline { 2 - 6 } & 2.02 & 2.53 & 3.05 & 3.88 & 4.50 \\
\cline { 2 - 7 } & 2.24 & 2.71 & 3.16 & 4.01 & 4.43 \\
\cline { 2 - 6 } & 1.95 & 2.62 & 3.30 & 3.67 & 4.81 \\
\hline
\end{tabular}
12.For both methods of Problem 10, plot the control chart described in this chapter. What meth the control chart suggest to use?
13. The demand for a product during a year was as follows:
\begin{tabular}{|l|l|l|l|l|l|l|l|l|l|l|l|l|}
\hline t & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 & 12 \\
\hline D & 80 & 100 & 79 & 98 & 95 & 104 & 80 & 98 & 102 & 96 & 115 & 88 \\
\hline
\end{tabular}
a) After determining the parameters of the following forecasts from the above data (if, necessary use least squatted error method),plot the forecast error control chart for each of above-mentioned methods.
b) Suppose the demands for the next 12 months are \(90,105,97,100,117,101,103,95,87,80,78,79\) and continue one of the control charts. Is the forecaster acceptable?
14. After learning artificial neural networks of type Multilayer Perceptron (MLP), write some MATLAB commands for creating an MLP with two hidden layers and use Moore's data set in MATLAB to train it. Then simulate
\(\mathrm{y}=\left[\begin{array}{cccc}-0.2218 & -0.3979 & -0.5229 & -0.0458\end{array}\right]\)
related to moore(17:20,1:5) i.e. the rows 17 through 20 columns \(1: 5\) of the data set.

Hint: the following commands could be used iun MATLAB \({ }^{1}\); Creating MLP
net=newff(p,y,[111],\{'tansig','logsig', 'purelin'\})
instructions for training
input matrix: moore (1:16,1:5)
target vector: moore \((1: 16,6)\)
load moore;
\(\mathrm{p}=(\text { moore }(1: 16,1: 5))^{\prime} ;\)
\(\mathrm{T}=(\) moore \((1: 16,6))\) ';
net=train(shabake,p,T);
To simulate y :

\footnotetext{
\({ }^{1}\) These commands were edited by the Late F. M Pourhosseini, the student of our department.
}
p2=(moore(17:20,1:5))';
yhat=sim(net,p2)
Calculation of RMSE between y and yhat:
\(\mathrm{y}=[-0.2218-0.3979-0.5229-0.0458]\);
rmse \(=\) sqrt(mse( y -yhat) )
In general to forecast Vector y2 from Input Matrix P1 the MATLAB instructions for creating, training and simulation of an MLP with 1 hidden layer and using Matrix P as input and Vector y as target for training could written as follows:
\(\mathrm{P}=\ldots\);
\(\mathrm{y}=\ldots\). .'; \(^{\prime}\)
net=newff(P,y,[111],\{'tansig', 'tansig', 'purelin'\})
net.trainparam.epochs=100;
net=train(net,P,y);
P1=...;
yhat=sim(net,P1);
y2=[...];
rmse=sqrt(mse(y2-yhat))
The last instruction calculates the root mean squared error of given vector and its forecast by the MLP.

\section*{If youth but knew, If old age but could,}

Si jeunesse savait, Si vieillesse pouvait, (French proverb)

\section*{}

The author received his B.S. in Industrial Engineering (IE) from Sharif University of Technology in Tehran, in 1976 and his MS degree in IE from University of Pittsburgh(Pitt) ,PA in 1978. He was employed as a faculty member in Kerman, Iran in 1979 and received PhD from Brunel University of London in July 2006. He has taught some courses including "Inventory control and planning \(I^{\prime \prime}\) to industrial engineering students.

The author has published some textbooks in Persian and English; some articles in international conferences and journals and supervised several B.S. and graduate theses. He was retired in 2015 for age from his job as a faculty member at a university in his hometown Kerman, Iran. Chairman of industrial and mechanical Engineering departments are among his responsibilities at the College of Engineering of Shahid Bahonar University of Kerman, Iran.```
